TITLE: RELATIVELY UNIQUE ID IN INTEGRATED CIRCUIT

FIELD OF INVENTION

5

35

40

The present invention relates to securing a series of integrated circuits against certain forms of security attacks.

The invention has primarily been developed for use in a printer controller chip to authenticate

communications between, for example, the printer controller and other peripheral devices such as ink cartridges. However, it will be appreciated that the invention can be applied to integrated circuits in other fields in which analogous problems are faced.

15 BACKGROUND OF INVENTION

Manufacturing a printhead that has relatively high resolution and print-speed raises a number of problems.

- Difficulties in manufacturing pagewidth printheads of any substantial size arise due to the relatively small dimensions of standard silicon wafers that are used in printhead (or printhead module) manufacture. For example, if it is desired to make an 8 inch wide pagewidth printhead, only one such printhead can be laid out on a standard 8-inch wafer, since such wafers are circular in plan. Manufacturing a pagewidth printhead from two or more smaller modules can reduce this limitation to some extent, but raises other problems related to providing a joint between adjacent printhead modules that is precise enough to avoid visible artefacts (which would typically take the form of noticeable lines) when the printhead is used. The problem is exacerbated in relatively high-resolution applications because of the tight tolerances dictated by the small spacing between nozzles.
- The quality of a joint region between adjacent printhead modules relies on factors including a precision with which the abutting ends of each module can be manufactured, the accuracy with which they can be aligned when assembled into a single printhead, and other more practical factors such as management of ink channels behind the nozzles. It will be appreciated that the difficulties include relative vertical displacement of the printhead modules with respect to each other.

Whilst some of these issues may be dealt with by careful design and manufacture, the level of precision required renders it relatively expensive to manufacture printheads within the required tolerances. It would be desirable to provide a solution to one or more of the problems associated with precision manufacture and assembly of multiple printhead modules to form a printhead, and especially a pagewidth printhead.

In some cases, it is desirable to produce a number of different printhead module types or lengths on a substrate to maximise usage of the substrate's surface area. However, different sizes and types of modules will have different numbers and layouts of print nozzles, potentially including different horizontal and vertical offsets. Where two or more modules are to be joined to form a single printhead, there is also the problem of dealing with different seam shapes between abutting ends of joined modules, which again may incorporate vertical or horizontal offsets between the modules. Printhead controllers are usually dedicated application specific integrated circuits (ASICs) designed for specific use with a single type of printhead module, that is used by itself rather than with other modules. It would be desirable to provide a way in which different lengths and types of printhead modules could be accounted for using a single printer controller.

Printer controllers face other difficulties when two or more printhead modules are involved, especially if it is desired to send dot data to each of the printheads directly (rather than via a single printhead connected to the controller). One concern is that data delivered to different length controllers at the same rate will cause the shorter of the modules to be ready for printing before any longer modules. Where there is little difference involved, the issue may not be of importance, but for large length differences, the result is that the bandwidth of a shared memory from which the dot data is supplied to the modules is effectively left idle once one of the modules is full and the remaining module or modules is still being filled. It would be desirable to provide a way of improving memory bandwidth usage in a system comprising a plurality of printhead modules of uneven length.

In any printing system that includes multiple nozzles on a printhead or printhead module, there is the possibility of one or more of the nozzles failing in the field, or being inoperative due to manufacturing defect. Given the relatively large size of a typical printhead module, it would be desirable to provide some form of compensation for one or more "dead" nozzles. Where the printhead also outputs fixative on a per-nozzle basis, it is also desirable that the fixative is provided in such a way that dead nozzles are compensated for.

A printer controller can take the form of an integrated circuit, comprising a processor and one or more peripheral hardware units for implementing specific data manipulation functions. A number of these units and the processor may need access to a common resource such as memory. One way of arbitrating between multiple access requests for a common resource is timeslot arbitration, in which access to the resource is guaranteed to a particular requestor during a predetermined timeslot.

One difficulty with this arrangement lies in the fact that not all access requests make the same demands on the resource in terms of timing and latency. For example, a memory read requires that data be fetched from memory, which may take a number of cycles, whereas a memory write can commence immediately. Timeslot arbitration does not take into account these differences, which may result in accesses being performed in a less efficient manner than might otherwise be the case. It would be desirable to provide a

PEA24US 2

5

10

15

20

25

30

35

40

timeslot arbitration scheme that improved this efficiency as compared with prior art timeslot arbitration schemes.

Also of concern when allocating resources in a timeslot arbitration scheme is the fact that the priority of an access request may not be the same for all units. For example, it would be desirable to provide a timeslot arbitration scheme in which one requestor (typically the memory) is granted special priority such that its requests are dealt with earlier than would be the case in the absence of such priority.

5

10

15

20

25

30

35

40

In systems that use a memory and cache, a cache miss (in which an attempt to load data or an instruction from a cache fails) results in a memory access followed by a cache update. It is often desirable when updating the cache in this way to update data other than that which was actually missed. A typical example would be a cache miss for a byte resulting in an entire word or line of the cache associated with that byte being updated. However, this can have the effect of tying up bandwidth between the memory (or a memory manager) and the processor where the bandwidth is such that several cycles are required to transfer the entire word or line to the cache. It would be desirable to provide a mechanism for updating a cache that improved cache update speed and/or efficiency.

Most integrated circuits an externally provided signal as (or to generate) a clock, often provided from a dedicated clock generation circuit. This is often due to the difficulties of providing an onboard clock that can operate at a speed that is predictable. Manufacturing tolerances of such on-board clock generation circuitry can result in clock rates that vary by a factor of two, and operating temperatures can increase this margin by an additional factor of two. In some cases, the particular rate at which the clock operates is not of particular concern. However, where the integrated circuit will be writing to an internal circuit that is sensitive to the time over which a signal is provided, it may be undesirable to have the signal be applied for too long or short a time. For example, flash memory is sensitive to being written too for too long a period. It would be desirable to provide a mechanism for adjusting a rate of an on-chip system clock to take into account the impact of manufacturing variations on clockspeed.

One form of attacking a secure chip is to induce (usually by increasing) a clock speed that takes the logic outside its rated operating frequency. One way of doing this is to reduce the temperature of the integrated circuit, which can cause the clock to race. Above a certain frequency, some logic will start malfunctioning. In some cases, the malfunction can be such that information on the chip that would otherwise be secure may become available to an external connection. It would be desirable to protect an integrated circuit from such attacks.

In an integrated circuit comprising non-volatile memory, a power failure can result in unintentional behaviour. For example, if an address or data becomes unreliable due to falling voltage supplied to the circuit but there is still sufficient power to cause a write, incorrect data can be written. Even worse, the data (incorrect or not) could be written to the wrong memory. The problem is exacerbated with multiword writes. It would be desirable to provide a mechanism for reducing or preventing spurious writes

when power to an integrated circuit is failing.

5

15

20

25

30

35

In an integrated circuit, it is often desirable to reduce unauthorised access to the contents of memory. This is particularly the case where the memory includes a key or some other form of security information that allows the integrated circuit to communicate with another entity (such as another integrated circuit, for example) in a secure manner. It would be particularly advantageous to prevent attacks involving direct probing of memory addresses by physically investigating the chip (as distinct from electronic or logical attacks via manipulation of signals and power supplied to the integrated circuit).

It is also desirable to provide an environment where the manufacturer of the integrated circuit (or some other authorised entity) can verify or authorize code to be run on an integrated circuit.

Another desideratum would be the ability of two or more entities, such as integrated circuits, to communicate with each other in a secure manner. It would also be desirable to provide a mechanism for secure communication between a first entity and a second entity, where the two entities, whilst capable of some form of secure communication, are not able to establish such communication between themselves.

In a system that uses resources (such as a printer, which uses inks) it may be desirable to monitor and update a record related to resource usage. Authenticating ink quality can be a major issue, since the attributes of inks used by a given printhead can be quite specific. Use of incorrect ink can result in anything from misfiring or poor performance to damage or destruction of the printhead. It would therefore be desirable to provide a system that enables authentication of the correct ink being used, as well as providing various support systems secure enabling refilling of ink cartridges.

In a system that prevents unauthorized programs from being loaded onto or run on an integrated circuit, it can be laborious to allow developers of software to access the circuits during software development. Enabling access to integrated circuits of a particular type requires authenticating software with a relatively high-level key. Distributing the key for use by developers is inherently unsafe, since a single leak of the key outside the organization could endanger security of all chips that use a related key to authorize programs. Having a small number of people with high-security clearance available to authenticate programs for testing can be inconvenient, particularly in the case where frequent incremental changes in programs during development require testing. It would be desirable to provide a mechanism for allowing access to one or more integrated circuits without risking the security of other integrated circuits in a series of such integrated circuits.

In symmetric key security, a message, denoted by M, is *plaintext*. The process of transforming M into *ciphertext* C, where the substance of M is hidden, is called *encryption*. The process of transforming C back into M is called *decryption*. Referring to the encryption function as E, and the decryption function as D, we have the following identities:

$$E[M] = C$$
$$D[C] = M$$

Therefore the following identity is true:

$$D[E[M]] = M$$

A symmetric encryption algorithm is one where:

- the encryption function E relies on key K₁,
- the decryption function D relies on key K_2 ,
- 10 K₂ can be derived from K₁, and
 - K₁ can be derived from K₂.

In most symmetric algorithms, K_1 equals K_2 . However, even if K_1 does not equal K_2 , given that one key can be derived from the other, a single key K can suffice for the mathematical definition. Thus:

15

$$E_K[M] = C$$

$$D_K[C] = M$$

The security of these algorithms rests very much in the key K. Knowledge of K allows *anyone* to encrypt or decrypt. Consequently K must remain a secret for the duration of the value of M. For example, M may be a wartime message "My current position is grid position 123-456". Once the war is over the value of M is greatly reduced, and if K is made public, the knowledge of the combat unit's position may be of no relevance whatsoever. The security of the particular symmetric algorithm is a function of two things: the strength of the algorithm and the length of the key.

25

20

An asymmetric encryption algorithm is one where:

- the encryption function E relies on key K_1 ,
- the decryption function D relies on key K₂,
- K₂ cannot be derived from K₁ in a reasonable amount of time, and
- K₁ cannot be derived from K₂ in a reasonable amount of time.

30

35

Thus:

$$E_{K1}[M] = C$$
$$D_{K2}[C] = M$$

These algorithms are also called *public-key* because one key K_1 can be made public. Thus anyone can encrypt a message (using K_1) but only the person with the corresponding decryption key (K_2) can decrypt and thus read the message.

In most cases, the following identity also holds:

$$E_{K2}[M] = C$$
$$D_{K1}[C] = M$$

5

10

15

20

25

30

35

This identity is very important because it implies that anyone with the public key K_1 can see M and know that it came from the owner of K_2 . No-one else could have generated C because to do so would imply knowledge of K_2 . This gives rise to a different application, unrelated to encryption - digital signatures.

A number of public key cryptographic algorithms exist. Most are impractical to implement, and many generate a very large C for a given M or require enormous keys. Still others, while secure, are far too slow to be practical for several years. Because of this, many public key systems are hybrid - a public key mechanism is used to transmit a symmetric session key, and then the session key is used for the actual messages.

All of the algorithms have a problem in terms of key selection. A random number is simply not secure enough. The two large primes p and q must be chosen carefully - there are certain weak combinations that can be factored more easily (some of the weak keys can be tested for). But nonetheless, key selection is not a simple matter of randomly selecting 1024 bits for example. Consequently the key selection process must also be secure.

Symmetric and asymmetric schemes both suffer from a difficulty in allowing establishment of multiple relationships between one entity and a two or more others, without the need to provide multiple sets of keys. For example, if a main entity wants to establish secure communications with two or more additional entities, it will need to maintain a different key for each of the additional entities. For practical reasons, it is desirable to avoid generating and storing large numbers of keys. To reduce key numbers, two or more of the entities may use the same key to communicate with the main entity. However, this means that the main entity cannot be sure which of the entities it is communicating with. Similarly, messages from the main entity to one of the entities can be decrypted by any of the other entities with the same key. It would be desirable if a mechanism could be provided to allow secure communication between a main entity and one or more other entities that overcomes at least some of the shortcomings of prior art.

In a system where a first entity is capable of secure communication of some form, it may be desirable to establish a relationship with another entity without providing the other entity with any information related the first entity's security features. Typically, the security features might include a key or a cryptographic function. It would be desirable to provide a mechanism for enabling secure communications between a first and second entity when they do not share the requisite secret function, key or other relationship to enable them to establish trust.

A number of other aspects, features, preferences and embodiments are disclosed in the Detailed

Description of the Preferred Embodiment below.

SUMMARY OF THE INVENTION

In accordance with a first aspect of the present invention, there is provided a method of manufacturing a series of integrated circuits having related functionality, the method including the steps of:

(a) determining an identifier;

5

10

15

20

25

30

- (b) permanently storing the identifier on one of the integrated circuits;
- (c) repeating steps (a) and (b) for each integrated circuit in the series;

wherein the identifiers for the series are determined in such a way that knowing the identifier of one of the integrated circuits does not improve the ability of an attacker to determine the identifier of any of the other integrated circuits.

Preferably, the identifier for each integrated circuit is determined using a stochastic mechanism, thereby rendering highly improbable the replication of some or all of the series of identifiers stored on the series of the integrated circuits.

In accordance with a second aspect of the invention, there is provided a series of integrated circuits having related functionality, wherein each of the integrated circuits incorporates an identifier determined and stored in accordance with the first aspect.

Preferably, each of the integrated circuits is a printer controller.

In accordance with a third aspect of the invention, there is provided a first integrated circuit of a series of integrated circuits according to the second aspect, operable in first and second mode, wherein in the first mode, supervisor code can access the identifier and in the second mode, user code cannot access the identifier.

Preferably, the supervisor mode is available to a program upon verification of that program by a boot program of the integrated circuit.

Preferably, the identifier is mapped into a key K.

Preferably, K is the identifier.

Preferably, K is created by applying a hash function or one-way function to the identifier.

Preferably, the integrated circuit is configured to produce and output a message, the message including a result of encrypting K.

In accordance with a fourth aspect of the invention, there is provided a method of injecting a key into a target integrated circuit, comprising the step of receiving the message generated by the first integrated circuit of claim 10, and transferring a second key into the target integrated circuit, the second key being based on K.

5

20

Preferably, the method includes generating the second key by manipulating K with a function.

More preferably, the function uses K and a code associated with the target integrated circuit as operands.

Preferably, the code is a code that is relatively unique to the target integrated circuit.

Preferably, K and the second key enable secure communication between the first integrated circuit and the target integrated circuit.

Preferably, the second integrated circuit is configured to communicate securely with a third integrated circuit, thereby enabling it to act as an intermediary between the first integrated circuit and the third integrated circuit, allowing secure communication therebetween.

Preferably, the first integrated circuit and the third integrated circuit do not share a key for use in the secure communication.

Preferably, the first integrated circuit is a printer controller configured to perform an authenticated read of the third integrated circuit by securely communicating via the second integrated circuit.

25 Preferably, the authenticated read relates to monitoring or updating usage of a resource.

BRIEF DESCRIPTION OF THE DRAWINGS

Preferred and other embodiments of the invention will now be described, by way of example only, with reference to the accompanying drawings, in which:

DETAILED DESCRIPTION OF PREFERRED AND OTHER EMBODIMENTS

It will be appreciated that the detailed description that follows takes the form of a highly detailed design of the invention, including supporting hardware and software. A high level of detailed disclosure is provided to ensure that one skilled in the art will have ample guidance for implementing the invention.

Imperative phrases such as "must", "requires", "necessary" and "important" (and similar language) should be read as being indicative of being necessary only for the preferred embodiment actually being described. As such, unless the opposite is clear from the context, imperative wording should not be interpreted as such. Nothing in the detailed description is to be understood as limiting the scope of the invention, which is intended to be defined as widely as is defined in the accompanying claims.

Indications of expected rates, frequencies, costs, and other quantitative values are exemplary and estimated only, and are made in good faith. Nothing in this specification should be read as implying that a particular commercial embodiment is or will be capable of a particular performance level in any measurable area.

It will be appreciated that the principles, methods and hardware described throughout this document can be applied to other fields. Much of the security-related disclosure, for example, can be applied to many other fields that require secure communications between entities, and certainly has application far beyond the field of printers.

SYSTEM OVERVIEW

5

10

15

35

40

The preferred of the present invention is implemented in a printer using microelectromechanical systems (MEMS) printheads. The printer can receive data from, for example, a personal computer such as an IBM compatible PC or Apple computer. In other embodiments, the printer can receive data directly from, for example, a digital still or video camera. The particular choice of communication link is not important, and can be based, for example, on USB, Firewire, Bluetooth or any other wireless or hardwired communications protocol.

PRINT SYSTEM OVERVIEW

3 Introduction

This document describes the SoPEC (Small office home office Print Engine Controller) ASIC (Application Specific Integrated Circuit) suitable for use in, for example, SoHo printer products. The SoPEC ASIC is intended to be a low cost solution for bi-lithic printhead control, replacing the multichip solutions in larger more professional systems with a single chip. The increased cost competitiveness is achieved by integrating several systems such as a modified PEC1 printing pipeline, CPU control system, peripherals and memory sub-system onto one SoC ASIC, reducing component count and simplifying board design.

This section will give a general introduction to Memjet printing systems, introduce the components that make a bi-lithic printhead system, describe possible system architectures and show how several SoPECs can be used to achieve A3 and A4 duplex printing. The section "SoPEC ASIC" describes the SoC SoPEC ASIC, with subsections describing the CPU, DRAM and Print Engine Pipeline subsystems. Each section gives a detailed description of the blocks used and their operation within the overall print system. The final section describes the bi-lithic printhead construction and associated implications to the system due to its makeup.

10 4 Nomenclature

4.1 BI-LITHIC PRINTHEAD NOTATION

A bi-lithic based printhead is constructed from 2 printhead ICs of varying sizes. The notation M:N is used to express the size relationship of each IC, where M specifies one printhead IC in inches and N specifies the remaining printhead IC in inches.

15

40

5

The 'SoPEC/MoPEC Bilithic Printhead Reference' document [10] contains a description of the bilithic printhead and related terminology.

4.2 DEFINITIONS

	T.Z DELIMITIONS			
20	The following terms a	are used throughout this specification:		
	Bi-lithic printhead	Refers to printhead constructed from 2 printhead ICs		
	CPU	Refers to CPU core, caching system and MMU.		
	ISI-Bridge chip	A device with a high speed interface (such as USB2.0, Ethernet or		
		IEEE1394) and one or more ISI interfaces. The ISI-Bridge would be the		
25		ISIMaster for each of the ISI buses it interfaces to.		
	ISIMaster	The ISIMaster is the only device allowed to initiate communication on the		
		Inter Sopec Interface (ISI) bus. The ISIMaster interfaces with the host.		
	ISISlave	Multi-SoPEC systems will contain one or more ISISlave SoPECs connected		
		to the ISI bus. ISISlaves can only respond to communication initiated by the		
30		ISIMaster.		
	LEON	Refers to the LEON CPU core.		
	LineSyncMaster	The LineSyncMaster device generates the line synchronisation pulse that all		
		SoPECs in the system must synchronise their line outputs to.		
	Multi-SoPEC	Refers to SoPEC based print system with multiple SoPEC devices		
35	Netpage	Refers to page printed with tags (normally in infrared ink).		
	PEC1	Refers to Print Engine Controller version 1, precursor to SoPEC used to		
		control printheads constructed from multiple angled printhead segments.		
	Printhead IC	Single MEMS IC used to construct bi-lithic printhead		
	PrintMaster	The PrintMaster device is responsible for coordinating all aspects of the print		
		•		

operation. There may only be one PrintMaster in a system.

QA Chip

Quality Assurance Chip

Storage SoPEC

An ISISlave SoPEC used as a DRAM store and which does not print.

Tag

Refers to pattern which encodes information about its position and orientation

which allow it to be optically located and its data contents read.

5 4.3 ACRONYM AND ABBREVIATIONS

The following acronyms and abbreviations are used in this specification

CFU

Contone FIFO Unit

CPU

Central Processing Unit

DIU

DRAM Interface Unit

10 DNC

4.4 PSEUDOCODE NOTATION

In general the pseudocode examples use C like statements with some exceptions.

Symbol and naming convections used for pseudocode.

//

Comment

40 =

Assignment

==,!=,<,> Operator equal, not equal, less than, greater than

+,-,*,/,% Operator addition, subtraction, multiply, divide, modulus

&,|,^,<<,>>,~ Bitwise AND, bitwise OR, bitwise exclusive OR, left shift, right shift, complement

AND, OR, NOT Logical AND, Logical OR, Logical inversion

5 [XX:YY] Array/vector specifier

{a, b, c} Concatenation operation

++, -- Increment and decrement

4.4.1 Register and signal naming conventions

In general register naming uses the C style conventions with capitalization to denote word delimiters. Signals use RTL style notation where underscore denote word delimiters. There is a direct translation between both convention. For example the *CmdSourceFifo* register is equivalent to *cmd_source_fifo* signal.

4.5 STATE MACHINE NOTATION

10

15

35

40

State machines should be described using the pseudocode notation outlined above. State machine descriptions use the convention of <u>underline</u> to indicate the cause of a transition from one state to another and plain text (no underline) to indicate the effect of the transition i.e. signal transitions which occur when the new state is entered.

A sample state machine is shown in Figure 1.

- 5 Printing Considerations
- A bi-lithic printhead produces 1600 dpi bi-level dots. On low-diffusion paper, each ejected drop forms a 22.5μm diameter dot. Dots are easily produced in isolation, allowing dispersed-dot dithering to be exploited to its fullest. Since the bi-lithic printhead is the width of the page and operates with a constant paper velocity, color planes are printed in perfect registration, allowing ideal dot-on-dot printing. Dot-on-dot printing minimizes 'muddying' of midtones caused by inter-color bleed.
- A page layout may contain a mixture of images, graphics and text. Continuous-tone (contone) images and graphics are reproduced using a stochastic dispersed-dot dither. Unlike a clustered-dot (or amplitude-modulated) dither, a *dispersed-dot* (or frequency-modulated) dither reproduces high spatial frequencies (i.e. image detail) almost to the limits of the dot resolution, while simultaneously reproducing lower spatial frequencies to their full color depth, when spatially integrated by the eye.
- A *stochastic* dither matrix is carefully designed to be free of objectionable low-frequency patterns when tiled across the image. As such its size typically exceeds the minimum size required to support a particular number of intensity levels (e.g. 16×16× 8 bits for 257 intensity levels).

Human contrast sensitivity peaks at a spatial frequency of about 3 cycles per degree of visual field and then falls off logarithmically, decreasing by a factor of 100 beyond about 40 cycles per degree and becoming immeasurable beyond 60 cycles per degree [25][25]. At a normal viewing distance of 12 inches (about 300mm), this translates roughly to 200-300 cycles per inch (cpi) on the printed page, or 400-600 samples per inch according to Nyquist's theorem.

In practice, contone resolution above about 300 ppi is of limited utility outside special applications such as medical imaging. Offset printing of magazines, for example, uses contone resolutions in the range 150 to 300 ppi. Higher resolutions contribute slightly to color error through the dither.

Black text and graphics are reproduced directly using bi-level black dots, and are therefore not antialiased (i.e. low-pass filtered) before being printed. Text should therefore be *supersampled* beyond the perceptual limits discussed above, to produce smoother edges when spatially integrated by the eye. Text resolution up to about 1200 dpi continues to contribute to perceived text sharpness (assuming low-diffusion paper, of course).

A Netpage printer, for example, may use a contone resolution of 267 ppi (i.e. 1600 dpi / 6), and a black text and graphics resolution of 800 dpi. A high end office or departmental printer may use a contone resolution of 320 ppi (1600 dpi / 5) and a black text and graphics resolution of 1600 dpi. Both formats are capable of exceeding the quality of commercial (offset) printing and photographic reproduction.

- 6 Document Data Flow
- 6.1 CONSIDERATIONS

5

10

15

20

25

30

35

Because of the page-width nature of the bi-lithic printhead, each page must be printed at a constant speed to avoid creating visible artifacts. This means that the printing speed can't be varied to match the input data rate. Document rasterization and document printing are therefore decoupled to ensure the printhead has a constant supply of data. A page is never printed until it is fully rasterized. This can be achieved by storing a compressed version of each rasterized page image in memory. This decoupling also allows the RIP(s) to run ahead of the printer when rasterizing simple pages, buying time to rasterize more complex pages.

Because contone color images are reproduced by stochastic dithering, but black text and line graphics are reproduced directly using dots, the compressed page image format contains a separate foreground bi-level black layer and background contone color layer. The black layer is composited over the contone layer after the contone layer is dithered (although the contone layer has an optional black component). A final layer of Netpage tags (in infrared or black ink) is optionally added to the page for printout.

Figure 2 shows the flow of a document from computer system to printed page.

At 267 ppi for example, a A4 page (8.26 inches × 11.7 inches) of contone CMYK data has a size of 26.3MB. At 320 ppi, an A4 page of contone data has a size of 37.8MB. Using lossy contone compression algorithms such as JPEG [27], contone images compress with a ratio up to 10:1 without noticeable loss of quality, giving compressed page sizes of 2.63MB at 267 ppi and 3.78 MB at 320 ppi.

At 800 dpi, a A4 page of bi-level data has a size of 7.4MB. At 1600 dpi, a Letter page of bi-level data has a size of 29.5 MB. Coherent data such as text compresses very well. Using lossless bi-level compression algorithms such as SMG4 fax as discussed in Section 8.1.2.3.1, ten-point plain text compresses with a ratio of about 50:1. Lossless bi-level compression across an average page is about 20:1 with 10:1 possible for pages which compress poorly. The requirement for SoPEC is to be able to print text at 10:1 compression. Assuming 10:1 compression gives compressed page sizes of 0.74 MB at 800 dpi, and 2.95 MB at 1600 dpi.

Once dithered, a page of CMYK contone image data consists of 116MB of bi-level data. Using lossless bi-level compression algorithms on this data is pointless precisely because the optimal dither is stochastic - i.e. since it introduces hard-to-compress disorder.

Netpage tag data is optionally supplied with the page image. Rather than storing a compressed bilevel data layer for the Netpage tags, the tag data is stored in its raw form. Each tag is supplied up to 120 bits of raw variable data (combined with up to 56 bits of raw fixed data) and covers up to a $6 \text{mm} \times 6 \text{mm}$ area (at 1600 dpi). The absolute maximum number of tags on a A4 page is 15,540 when the tag is only $2 \text{mm} \times 2 \text{mm}$ (each tag is 126 dots \times 126 dots, for a total coverage of 148 tags \times 105 tags). 15,540 tags of 128 bits per tag gives a compressed tag page size of 0.24 MB.

The multi-layer compressed page image format therefore exploits the relative strengths of lossy JPEG contone image compression, lossless bi-level text compression, and tag encoding. The format is compact enough to be storage-efficient, and simple enough to allow straightforward real-time expansion during printing.

Since text and images normally don't overlap, the normal worst-case page image size is image only, while the normal best-case page image size is text only. The addition of worst case Netpage tags adds 0.24MB to the page image size. The worst-case page image size is text over image plus tags. The average page size assumes a quarter of an average page contains images. Table 1 shows data sizes for compressed Letter page for these different options.

Table 1. Data sizes for A4 page (8.26 inches × 11.7 inches)

	267 ppi contone	320 ppi contone
	800 dpi bi-level	1600 dpi bi-level
Image only (contone), 10:1 compression	2.63 MB	3.78 MB
Text only (bi-level), 10:1 compression	0.74 MB	2.95 MB
Netpage tags, 1600 dpi	0.24 MB	0.24 MB
Worst case (text + image + tags)	3.61 MB	6.67 MB
Average (text + 25% image + tags)	1.64 MB	4.25 MB

6.2 DOCUMENT DATA FLOW

5

15

20

25

30

The Host PC rasterizes and compresses the incoming document on a page by page basis. The page is restructured into bands with one or more bands used to construct a page. The compressed data is then transferred to the SoPEC device via the USB link. A complete band is stored in SoPEC embedded memory. Once the band transfer is complete the SoPEC device reads the compressed data, expands the band, normalizes contone, bi-level and tag data to 1600 dpi and transfers the resultant calculated dots to the bi-lithic printhead.

The document data flow is

- The RIP software rasterizes each page description and compress the rasterized page image.
- The infrared layer of the printed page optionally contains encoded Netpage [5] tags at a programmable density.

- The compressed page image is transferred to the SoPEC device via the USB normally on a band by band basis.
- The print engine takes the compressed page image and starts the page expansion.
- The first stage page expansion consists of 3 operations performed in parallel
- expansion of the JPEG-compressed contone layer
 - expansion of the SMG4 fax compressed bi-level layer
 - encoding and rendering of the bi-level tag data.
 - The second stage dithers the contone layer using a programmable dither matrix, producing up to four bi-level layers at full-resolution.
- The second stage then composites the bi-level tag data layer, the bi-level SMG4 fax decompressed layer and up to four bi-level JPEG de-compressed layers into the full-resolution page image.
 - A fixative layer is also generated as required.

15

25

30

35

 The last stage formats and prints the bi-level data through the bi-lithic printhead via the printhead interface.

The SoPEC device can print a full resolution page with 6 color planes. Each of the color planes can be generated from compressed data through any channel (either JPEG compressed, bi-level SMG4 fax compressed, tag data generated, or fixative channel created) with a maximum number of 6 data channels from page RIP to bi-lithic printhead color planes.

The mapping of data channels to color planes is programmable, this allows for multiple color planes in the printhead to map to the same data channel to provide for redundancy in the printhead to assist dead nozzle compensation.

Also a data channel could be used to gate data from another data channel. For example in stencil mode, data from the bilevel data channel at 1600 dpi can be used to filter the contone data channel at 320 dpi, giving the effect of 1600 dpi contone image.

6.3 PAGE CONSIDERATIONS DUE TO SOPEC

The SoPEC device typically stores a complete page of document data on chip. The amount of storage available for compressed pages is limited to 2Mbytes, imposing a fixed maximum on compressed page size. A comparison of the compressed image sizes in Table 2 indicates that SoPEC would not be capable of printing worst case pages unless they are split into bands and printing commences before all the bands for the page have been downloaded. The page sizes in the table are shown for comparison purposes and would be considered reasonable for a professional level printing system. The SoPEC device is aimed at the consumer level and would not be required to print pages of that complexity. Target document types for the SoPEC device are shown Table 2.

Table 2. Page content targets for SoPEC

Page Content Description	Calculation	Size

If a document with more complex pages is required, the page RIP software in the host PC can determine that there is insufficient memory storage in the SoPEC for that document. In such cases the RIP software can take two courses of action. It can increase the compression ratio until the compressed page size will fit in the SoPEC device, at the expense of document quality, or divide the page into bands and allow SoPEC to begin printing a page band before all bands for that page are downloaded. Once SoPEC starts printing a page it cannot stop, if SoPEC consumes compressed data faster than the bands can be downloaded a buffer underrun error could occur causing the print to fail. A buffer underrun occurs if a line synchronisation pulse is received before a line of data has been transferred to the printhead.

Other options which can be considered if the page does not fit completely into the compressed page store are to slow the printing or to use multiple SoPECs to print parts of the page. A Storage SoPEC (Section 7.2.5) could be added to the system to provide guaranteed bandwidth data delivery. The print system could also be constructed using an ISI-Bridge chip (Section 7.2.6) to provide guaranteed data delivery.

7 Memiet Printer Architecture

5

10

15

30

The SoPEC device can be used in several printer configurations and architectures.

In the general sense every SoPEC based printer architecture will contain:

- One or more SoPEC devices.
- One or more bi-lithic printheads.
 - Two or more LSS busses.
 - Two or more QA chips.
 - USB 1.1 connection to host or ISI connection to Bridge Chip.
 - ISI bus connection between SoPECs (when multiple SoPECs are used).
- Some example printer configurations as outlined in Section 7.2. The various system components are outlined briefly in Section 7.1.
 - 7.1 SYSTEM COMPONENTS
 - 7.1.1 SoPEC Print Engine Controller

The SoPEC device contains several system on a chip (SoC) components, as well as the print engine pipeline control application specific logic.

7.1.1.1 Print Engine Pipeline (PEP) Logic

The PEP reads compressed page store data from the embedded memory, optionally decompresses the data and formats it for sending to the printhead. The print engine pipeline functionality includes expanding the page image, dithering the contone layer, compositing the black layer over the contone layer, rendering of Netpage tags, compensation for dead nozzles in the printhead, and sending the resultant image to the bi-lithic printhead.

7.1.1.2 Embedded CPU

5

10

15

20

SoPEC contains an embedded CPU for general purpose system configuration and management. The CPU performs page and band header processing, motor control and sensor monitoring (via the GPIO) and other system control functions. The CPU can perform buffer management or report buffer status to the host. The CPU can optionally run vendor application specific code for general print control such as paper ready monitoring and LED status update.

7.1.1.3 Embedded Memory Buffer

A 2.5Mbyte embedded memory buffer is integrated onto the SoPEC device, of which approximately 2Mbytes are available for compressed page store data. A compressed page is divided into one or more bands, with a number of bands stored in memory. As a band of the page is consumed by the PEP for printing a new band can be downloaded. The new band may be for the current page or the next page.

Using banding it is possible to begin printing a page before the complete compressed page is downloaded, but care must be taken to ensure that data is always available for printing or a buffer underrun may occur.

An Storage SoPEC acting as a memory buffer (Section 7.2.5) or an ISI-Bridge chip with attached DRAM (Section 7.2.6) could be used to provide guaranteed data delivery.

7.1.1.4 Embedded USB 1.1 Device

The embedded USB 1.1 device accepts compressed page data and control commands from the host PC, and facilitates the data transfer to either embedded memory or to another SoPEC device in multi-SoPEC systems.

7.1.2 Bi-lithic Printhead

The printhead is constructed by abutting 2 printhead ICs together. The printhead ICs can vary in size from 2 inches to 8 inches, so to produce an A4 printhead several combinations are possible.

For example two printhead ICs of 7 inches and 3 inches could be used to create a A4 printhead (the notation is 7:3). Similarly 6 and 4 combination (6:4), or 5:5 combination. For an A3 printhead it can be constructed from 8:6 or an 7:7 printhead IC combination. For photographic printing smaller printheads can be constructed.

7.1.3 LSS interface bus

Each SoPEC device has 2 LSS system buses for communication with QA devices for system authentication and ink usage accounting. The number of QA devices per bus and their position in the system is unrestricted with the exception that *PRINTER_QA* and *INK_QA* devices should be on separate LSS busses.

7.1.4 QA devices

Each SoPEC system can have several QA devices. Normally each printing SoPEC will have an associated *PRINTER_QA*. Ink cartridges will contain an *INK_QA* chip. *PRINTER_QA* and *INK_QA* devices should be on separate LSS busses. All QA chips in the system are physically identical with flash memory contents defining *PRINTER_QA* from *INK_QA* chip.

5 7.1.5 ISI interface

The Inter-SoPEC Interface (ISI) provides a communication channel between SoPECs in a multi-SoPEC system. The ISIMaster can be SoPEC device or an ISI-Bridge chip depending on the printer configuration. Both compressed data and control commands are transferred via the interface.

7.1.6 ISI-Bridge Chip

- A device, other than a SoPEC with a USB connection, which provides print data to a number of slave SoPECs. A bridge chip will typically have a high bandwidth connection, such as USB2.0, Ethernet or IEEE1394, to a host and may have an attached external DRAM for compressed page storage. A bridge chip would have one or more ISI interfaces. The use of multiple ISI buses would allow the construction of independent print systems within the one printer. The ISI-Bridge would be the ISIMaster for each of the ISI buses it interfaces to.
 - 7.2 Possible Sopec Systems

Several possible SoPEC based system architectures exist. The following sections outline some possible architectures. It is possible to have extra SoPEC devices in the system used for DRAM storage. The QA chip configurations shown are indicative of the flexibility of LSS bus architecture,

but not limited to those configurations.

25

40

7.2.1 A4 Simplex with 1 SoPEC device

In Figure 3, a single SoPEC device can be used to control two printhead ICs. The SoPEC receives compressed data through the USB device from the host. The compressed data is processed and transferred to the printhead.

7.2.2 A4 Duplex with 2 SoPEC devices

In Figure 4, two SoPEC devices are used to control two bi-lithic printheads, each with two printhead ICs. Each bi-lithic printhead prints to opposite sides of the same page to achieve duplex printing. The SoPEC connected to the USB is the ISIMaster SoPEC, the remaining SoPEC is an ISISlave.

The ISIMaster receives all the compressed page data for both SoPECs and re-distributes the compressed data over the Inter-SoPEC Interface (ISI) bus.

It may not be possible to print an A4 page every 2 seconds in this configuration since the USB 1.1 connection to the host may not have enough bandwidth. An alternative would be for each SoPEC to have its own USB 1.1 connection. This would allow a faster average print speed.

35 7.2.3 A3 Simplex with 2 SoPEC devices

In Figure 5, two SoPEC devices are used to control one A3 bi-lithic printhead. Each SoPEC controls only one printhead IC (the remaining PHI port typically remains idle). This system uses the SoPEC with the USB connection as the ISIMaster. In this dual SoPEC configuration the compressed page store data is split across 2 SoPECs giving a total of 4Mbyte page store, this allows the system to

use compression rates as in an A4 architecture, but with the increased page size of A3. The ISIMaster receives all the compressed page data for all SoPECs and re-distributes the compressed data over the Inter-SoPEC Interface (ISI) bus.

It may not be possible to print an A3 page every 2 seconds in this configuration since the USB 1.1 connection to the host will only have enough bandwidth to supply 2Mbytes every 2 seconds. Pages which require more than 2MBytes every 2 seconds will therefore print more slowly. An alternative would be for each SoPEC to have its own USB 1.1 connection. This would allow a faster average print speed.

7.2.4 A3 Duplex with 4 SoPEC devices

5

20

40

- In Figure 6 a 4 SoPEC system is shown. It contains 2 A3 bi-lithic printheads, one for each side of an A3 page. Each printhead contain 2 printhead ICs, each printhead IC is controlled by an independent SoPEC device, with the remaining PHI port typically unused. Again the SoPEC with USB 1.1 connection is the ISIMaster with the other SoPECs as ISISlaves. In total, the system contains 8Mbytes of compressed page store (2Mbytes per SoPEC), so the increased page size does not degrade the system print quality, from that of an A4 simplex printer. The ISIMaster receives all the compressed page data for all SoPECs and re-distributes the compressed data over the Inter-SoPEC Interface (ISI) bus.
 - It may not be possible to print an A3 page every 2 seconds in this configuration since the USB 1.1 connection to the host will only have enough bandwidth to supply 2Mbytes every 2 seconds. Pages which require more than 2MBytes every 2 seconds will therefore print more slowly. An alternative would be for each SoPEC or set of SoPECs on the same side of the page to have their own USB 1.1 connection (as ISISlaves may also have direct USB connections to the host). This would allow a faster average print speed.
- 7.2.5 SoPEC DRAM storage solution: A4 Simplex with 1 printing SoPEC and 1 memory SoPEC Extra SoPECs can be used for DRAM storage e.g. in Figure 7 an A4 simplex printer can be built with a single extra SoPEC used for DRAM storage. The DRAM SoPEC can provide guaranteed bandwidth delivery of data to the printing SoPEC. SoPEC configurations can have multiple extra SoPECs used for DRAM storage.
 - 7.2.6 ISI-Bridge chip solution: A3 Duplex system with 4 SoPEC devices
- In Figure 8, an ISI-Bridge chip provides slave-only ISI connections to SoPEC devices. Figure 8 shows a ISI-Bridge chip with 2 separate ISI ports. The ISI-Bridge chip is the ISIMaster on each of the ISI busses it is connected to. All connected SoPECs are ISISlaves. The ISI-Bridge chip will typically have a high bandwidth connection to a host and may have an attached external DRAM for compressed page storage.
- An alternative to having a ISI-Bridge chip would be for each SoPEC or each set of SoPECs on the same side of a page to have their own USB 1.1 connection. This would allow a faster average print speed.
 - 8 Page Format and Printflow
 - When rendering a page, the RIP produces a page header and a number of bands (a non-blank page requires at least one band) for a page. The page header contains high level rendering

parameters, and each band contains compressed page data. The size of the band will depend on the memory available to the RIP, the speed of the RIP, and the amount of memory remaining in SoPEC while printing the previous band(s). Figure 9 shows the high level data structure of a number of pages with different numbers of bands in the page.

Each compressed band contains a mandatory band header, an optional bi-level plane, optional sets of interleaved contone planes, and an optional tag data plane (for Netpage enabled applications). Since each of these planes is optional¹, the band header specifies which planes are included with the band. Figure 10 gives a high-level breakdown of the contents of a page band.

10 A single SoPEC has maximum rendering restrictions as follows:

- 1 bi-level plane
- 1 contone interleaved plane set containing a maximum of 4 contone planes
- 1 tag data plane

30

35

- a bi-lithic printhead with a maximum of 2 printhead ICs
- 15 The requirement for single-sided A4 single SoPEC printing is
 - average contone JPEG compression ratio of 10:1, with a local minimum compression ratio of
 5:1 for a single line of interleaved JPEG blocks.
 - average bi-level compression ratio of 10:1, with a local minimum compression ratio of 1:1 for a single line.
- 20 If the page contains rendering parameters that exceed these specifications, then the RIP or the Host PC must split the page into a format that can be handled by a single SoPEC. In the general case, the SoPEC CPU must analyze the page and band headers and generate an appropriate set of register write commands to configure the units in SoPEC for that page. The various bands are passed to the destination SoPEC(s) to locations in DRAM determined by the host.

The host keeps a memory map for the DRAM, and ensures that as a band is passed to a SoPEC, it is stored in a suitable free area in DRAM. Each SoPEC is connected to the ISI bus or USB bus via its Serial communication Block (SCB). The SoPEC CPU configures the SCB to allow compressed data bands to pass from the USB or ISI through the SCB to SoPEC DRAM. Figure 11 shows an example data flow for a page destined to be printed by a single SoPEC. Band usage information is generated by the individual SoPECs and passed back to the host.

SoPEC has an addressing mechanism that permits circular band memory allocation, thus facilitating easy memory management. However it is not strictly necessary that all bands be stored together.

As long as the appropriate registers in SoPEC are set up for each band, and a given band is contiguous², the memory can be allocated in any way.

¹Although a band must contain at least one plane

²Contiguous allocation also includes wrapping around in SoPEC's band store memory.

8.1 PRINT ENGINE EXAMPLE PAGE FORMAT

This section describes a possible format of compressed pages expected by the embedded CPU in SoPEC. The format is generated by software in the host PC and interpreted by embedded software in SoPEC. This section indicates the type of information in a page format structure, but

5 implementations need not be limited to this format. The host PC can optionally perform the majority of the header processing.

The compressed format and the print engines are designed to allow real-time page expansion during printing, to ensure that printing is never interrupted in the middle of a page due to data underrun.

The page format described here is for a single black bi-level layer, a contone layer, and a Netpage tag layer. The black bi-level layer is defined to composite *over* the contone layer.

The black bi-level layer consists of a bitmap containing a 1-bit *opacity* for each pixel. This black layer *matte* has a resolution which is an integer or non-integer factor of the printer's dot resolution. The highest supported resolution is 1600 dpi, i.e. the printer's full dot resolution.

The contone layer, optionally passed in as YCrCb, consists of a 24-bit CMY or 32-bit CMYK color for each pixel. This contone image has a resolution which is an integer or non-integer factor of the printer's dot resolution. The requirement for a single SoPEC is to support 1 side per 2 seconds A4/Letter printing at a resolution of 267 ppi, i.e. one-sixth the printer's dot resolution.

Non-integer scaling can be performed on both the contone and bi-level images. Only integer scaling can be performed on the tag data.

The black bi-level layer and the contone layer are both in compressed form for efficient storage in the printer's internal memory.

8.1.1 Page structure

20

25

35

A single SoPEC is able to print with full edge bleed for Letter and A3 via different stitch part combinations of the bi-lithic printhead. It imposes no margins and so has a printable page area which corresponds to the size of its paper. The target page size is constrained by the printable page area, less the explicit (target) left and top margins specified in the page description. These relationships are illustrated below.

8.1.2 Compressed page format

Apart from being implicitly defined in relation to the printable page area, each page description is complete and self-contained. There is no data stored separately from the page description to which the page description refers.³ The page description consists of a page header which describes the size and resolution of the page, followed by one or more page bands which describe the actual page content.

8.1.2.1 Page header

Table 3 shows an example format of a page header.

³SoPEC relies on dither matrices and tag structures to have already been set up, but these are not considered to be part of a general page format. It is trivial to extend the page format to allow exact specification of dither matrices and tag structures.

Table 3. Page header format

field	format	description
signature	16-bit integer	Page header format signature.
version	16-bit integer	Page header format version number.
structure size	16-bit integer	Size of page header.
band count	16-bit integer	Number of bands specified for this page.
target resolution (dpi)	16-bit integer	Resolution of target page. This is always
		1600 for the Memjet printer.
target page width	16-bit integer	Width of target page, in dots.
target page height	32-bit integer	Height of target page, in dots.
target left margin for black and	16-bit integer	Width of target left margin, in dots, for black
contone		and contone.
target top margin for black and	16-bit integer	Height of target top margin, in dots, for black
contone		and contone.
target right margin for black and	16-bit integer	Width of target right margin, in dots, for black
contone		and contone.
target bottom margin for black	16-bit integer	Height of target bottom margin, in dots, for
and contone		black and contone.
target left margin for tags	16-bit integer	Width of target left margin, in dots, for tags.
target top margin for tags	16-bit integer	Height of target top margin, in dots, for tags.
target right margin for tags	16-bit integer	Width of target right margin, in dots, for tags.
target bottom margin for tags	16-bit integer	Height of target bottom margin, in dots, for
		tags.
generate tags	16-bit integer	Specifies whether to generate tags for this
		page (0 - no, 1 - yes).
fixed tag data	128-bit integer	This is only valid if generate tags is set.
tag vertical scale factor	16-bit integer	Scale factor in vertical direction from tag data
		resolution to target resolution. Valid range =
		1-511. Integer scaling only
tag horizontal scale factor	16-bit integer	Scale factor in horizontal direction from tag
		data resolution to target resolution. Valid
		range = 1-511. Integer scaling only.
bi-level layer vertical scale factor	16-bit integer	Scale factor in vertical direction from bi-level
		resolution to target resolution (must be 1 or
		greater). May be non-integer.
		Expressed as a fraction with upper 8-bits the
		numerator and the lower 8 bits the
		denominator.

or greater). May be non-integer. Expressed as a fraction with upper 8-bits the numerator and the lower 8 bits the denominator. bi-level layer page width 16-bit integer 32-bit integer 16 bit integer 16 bit integer Defines the color conversion that is required for the JPEG data. Bits 2-0 specify how many contone planes there are (e.g. 3 for CMY and 4 for CMYK). Bit 3 specifies whether the first 3 color planes need to be converted back from YCrCb to CMY. Only valid if b2-0 = 3 or 4. 0 - no conversion, leave JPEG colors alone 1 - color convert. Bits 7-4 specifies whether the YCrCb was generated directly from CMY, or whether it was converted to RGB first via the step: R = 255-C, G = 255-M, B = 255-Y. Each of the color planes can be individually inverted. Bit 4: 0 - do not invert color plane 0 1 - invert color plane 1 1 - invert color plane 1 1 - invert color plane 2 Bit 6: 0 - do not invert color plane 2 1 - invert color plane 3 1 - invert color plane 3 Bit 8 specifies whether the contone data is JPEG compressed or non-compressed: 0 - JPEG compressed 1 - non-compressed The remaining bits are reserved (0).	bi-level layer horizontal scale fac-	16-bit integer	Scale factor in horizontal direction from bi-
as a fraction with upper 8-bits the numerato and the lower 8 bits the denominator. Di-level layer page width 16-bit integer Width of bi-level layer page, in pixels. Height of bi-level layer page, in pixels. 16 bit integer Defines the color conversion that is required for the JPEG data. Bits 2-0 specify how many contone planes there are (e.g. 3 for CMY and 4 for CMYK). Bit 3 specifies whether the first 3 color planes need to be converted back from YCrCb to CMY. Only valid if b2-0 = 3 or 4. 0 - no conversion, leave JPEG colors alone 1 - color convert. Bits 7-4 specifies whether the YCrCb was generated directly from CMY, or whether it was converted to RGB first via the step. R = 255-C, G = 255-M, B = 255-Y. Each of the color planes can be individually inverted. channel resolution to target resolution. Valid	contone vertical scale factor	16-bit integer	Scale factor in vertical direction from contone
<u></u>		<u> </u>	channel resolution to target resolution. Valid

contone horizontal scale factor	16-bit integer	range = 1-255. May be non-integer. Expressed as a fraction with upper 8-bits the numerator and the lower 8 bits the denominator. Scale factor in horizontal direction from contone channel resolution to target resolution. Valid range = 1-255. May be non-integer. Expressed as a fraction with upper 8-bits the numerator and the lower 8 bits the denominator.
contone page width	16-bit integer	Width of contone page, in contone pixels.
contone page height	32-bit integer	Height of contone page, in contone pixels.
reserved	up to 128 bytes	Reserved and 0 pads out page header to multiple of 128 bytes.

The page header contains a signature and version which allow the CPU to identify the page header format. If the signature and/or version are missing or incompatible with the CPU, then the CPU can reject the page.

The contone flags define how many contone layers are present, which typically is used for defining whether the contone layer is CMY or CMYK. Additionally, if the color planes are CMY, they can be optionally stored as YCrCb, and further optionally color space converted from CMY directly or via RGB. Finally the contone data is specified as being either JPEG compressed or non-compressed.

The page header defines the resolution and size of the target page. The bi-level and contone layers are clipped to the target page if necessary. This happens whenever the bi-level or contone scale factors are not factors of the target page width or height.

The target left, top, right and bottom margins define the positioning of the target page within the printable page area.

The tag parameters specify whether or not Netpage tags should be produced for this page and what orientation the tags should be produced at (landscape or portrait mode). The fixed tag data is also provided.

The contone, bi-level and tag layer parameters define the page size and the scale factors.

8.1.2.2 Band format

5

20

Table 4 shows the format of the page band header.

Table 4. Band header format

field	format	description
signature	16-bit integer	Page band header format signature.

version	16-bit integer	Page band header format version number.
structure size	16-bit integer	Size of page band header.
bi-level layer band height	16-bit integer	Height of bi-level layer band, in black pixels.
bi-level layer band data size	32-bit integer	Size of bi-level layer band data, in bytes.
contone band height	16-bit integer	Height of contone band, in contone pixels.
contone band data size	32-bit integer	Size of contone plane band data, in bytes.
tag band height	16-bit integer	Height of tag band, in dots.
tag band data size	1	Size of unencoded tag data band, in bytes. Can be 0 which indicates that no tag data is provided.
reserved	up to 128 bytes	Reserved and 0 pads out band header to multiple of 128 bytes.

The bi-level layer parameters define the height of the black band, and the size of its compressed band data. The variable-size black data follows the page band header.

The contone layer parameters define the height of the contone band, and the size of its compressed page data. The variable-size contone data follows the black data.

The tag band data is the set of variable tag data half-lines as required by the tag encoder. The format of the tag data is found in Section 26.5.2. The tag band data follows the contone data.

Table 5 shows the format of the variable-size compressed band data which follows the page band header.

Table 5. Page band data format

field	format	Description
black data	Modified G4 facsimile bitstream ⁴	Compressed bi-level layer.
contone data	JPEG bytestream	Compressed contone datalayer.
tag data map	Tag data array	Tag data format. See Section 26.5.2.

The start of each variable-size segment of band data should be aligned to a 256-bit DRAM word boundary.

The following sections describe the format of the compressed bi-level layers and the compressed contone layer. section 26.5.1 on page 410 describes the format of the tag data structures.

8.1.2.3 Bi-level data compression

10

20

The (typically 1600 dpi) black bi-level layer is losslessly compressed using Silverbrook Modified Group 4 (SMG4) compression which is a version of Group 4 Facsimile compression [22] without Huffman and with simplified run length encodings. Typically compression ratios exceed 10:1. The encoding are listed in Table 6 and Table 7.

Table 6. Bi-Level group 4 facsimile style compression encodings

Encoding Description

same as Group 41000 Pass Command: a0 ← b2, skip next two edges

See section 8.1.2.3 on page 36 for note regarding the use of this standard

Facsimile				
			1	Vertical(0): a0 ← b1, color = !color
			110	Vertical(1): a0 ← b1 + 1, color = !color
			010	Vertical(-1): a0 ← b1 - 1, color = !color
			110000	Vertical(2): a0 ← b1 + 2, color = !color
			010000	Vertical(-2): a0 ← b1 - 2, color = !color
Unique	to	this	100000	Vertical(3): a0 ← b1 + 3, color = !color
implement	ation			
			000000	Vertical(-3): a0 ← b1 - 3, color = !color
			<rl><rl>100</rl></rl>	Horizontal: a0 ← a0 + <rl> + <rl></rl></rl>

SMG4 has a pass through mode to cope with local negative compression. Pass through mode is activated by a special run-length code. Pass through mode continues to either end of line or for a pre-programmed number of bits, whichever is shorter. The special run-length code is always executed as a run-length code, followed by pass through. The pass through escape code is a medium length run-length with a run of less than or equal to 31.

Table 7. Run length (RL) encodings

5

10

15

	Encoding	Description
Unique to this implementation	sRRRR1	Short Black Runlength (5 bits)
	RRRRR1	Short White Runlength (5 bits)
	RRRRRRRRR10	Medium Black Runlength (10 bits)
	RRRRRRR10	Medium White Runlength (8 bits)
	RRRRRRRRRR10	Medium Black Runlength with RRRRRRRRR <=
		31, Enter pass through
	RRRRRRR10	Medium White Runlength with RRRRRRR <=
		31, Enter pass through
	RRRRRRRRRRRRR00	Long Black Runlength (15 bits)
	RRRRRRRRRRRRRR00	Long White Runlength (15 bits)

Since the compression is a bitstream, the encodings are read right (least significant bit) to left (most significant bit). The run lengths given as RRRR in Table are read in the same way (least significant bit at the right to most significant bit at the left).

Each band of bi-level data is optionally self contained. The first line of each band therefore is based on a 'previous' blank line or the last line of the previous band.

8.1.2.3.1 Group 3 and 4 facsimile compression

The Group 3 Facsimile compression algorithm [22] losslessly compresses bi-level data for transmission over slow and noisy telephone lines. The bi-level data represents scanned black text and graphics on a white background, and the algorithm is tuned for this class of images (it is explicitly not tuned, for example, for *halftoned* bi-level images). The *1D* Group 3 algorithm

runlength-encodes each scanline and then Huffman-encodes the resulting runlengths. Runlengths in the range 0 to 63 are coded with terminating codes. Runlengths in the range 64 to 2623 are coded with make-up codes, each representing a multiple of 64, followed by a terminating code. Runlengths exceeding 2623 are coded with multiple make-up codes followed by a terminating code. 5 The Huffman tables are fixed, but are separately tuned for black and white runs (except for make-up codes above 1728, which are common). When possible, the 2D Group 3 algorithm encodes a scanline as a set of short edge deltas $(0, \pm 1, \pm 2, \pm 3)$ with reference to the previous scanline. The delta symbols are entropy-encoded (so that the zero delta symbol is only one bit long etc.) Edges within a 2D-encoded line which can't be delta-encoded are runlength-encoded, and are identified by 10 a prefix. 1D- and 2D-encoded lines are marked differently. 1D-encoded lines are generated at regular intervals, whether actually required or not, to ensure that the decoder can recover from line noise with minimal image degradation. 2D Group 3 achieves compression ratios of up to 6:1 [32]. The Group 4 Facsimile algorithm [22] losslessly compresses bi-level data for transmission over error-free communications lines (i.e. the lines are truly error-free, or error-correction is done at a 15 lower protocol level). The Group 4 algorithm is based on the 2D Group 3 algorithm, with the essential modification that since transmission is assumed to be error-free, 1D-encoded lines are no longer generated at regular intervals as an aid to error-recovery. Group 4 achieves compression ratios ranging from 20:1 to 60:1 for the CCITT set of test images [32].

The design goals and performance of the Group 4 compression algorithm qualify it as a compression algorithm for the bi-level layers. However, its Huffman tables are tuned to a lower scanning resolution (100-400 dpi), and it encodes runlengths exceeding 2623 awkwardly.

8.1.2.4 Contone data compression

20

25

30

35

The contone layer (CMYK) is either a non-compressed bytestream or is compressed to an interleaved JPEG bytestream. The JPEG bytestream is complete and self-contained. It contains all data required for decompression, including quantization and Huffman tables.

The contone data is optionally converted to YCrCb before being compressed (there is no specific advantage in color-space converting if not compressing). Additionally, the CMY contone pixels are optionally converted (on an individual basis) to RGB before color conversion using R=255-C, G=255-M, B=255-Y. Optional bitwise inversion of the K plane may also be performed. Note that this CMY to RGB conversion is not intended to be accurate for display purposes, but rather for the purposes of later converting to YCrCb. The inverse transform will be applied before printing. 8.1.2.4.1 JPEG compression

The JPEG compression algorithm [27] lossily compresses a contone image at a specified quality level. It introduces imperceptible image degradation at compression ratios below 5:1, and negligible image degradation at compression ratios below 10:1 [33].

JPEG typically first transforms the image into a color space which separates luminance and chrominance into separate color channels. This allows the chrominance channels to be subsampled without appreciable loss because of the human visual system's relatively greater sensitivity to luminance than chrominance. After this first step, each color channel is compressed separately.

The image is divided into 8×8 pixel blocks. Each block is then transformed into the frequency domain via a discrete cosine transform (DCT). This transformation has the effect of concentrating image energy in relatively lower-frequency coefficients, which allows higher-frequency coefficients to be more crudely quantized. This quantization is the principal source of compression in JPEG.

Further compression is achieved by ordering coefficients by frequency to maximize the likelihood of adjacent zero coefficients, and then runlength-encoding runs of zeroes. Finally, the runlengths and non-zero frequency coefficients are entropy coded. Decompression is the inverse process of compression.

8.1.2.4.2 Non-compressed format

10 If the contone data is non-compressed, it must be in a block-based format bytestream with the same pixel order as would be produced by a JPEG decoder. The bytestream therefore consists of a series of 8×8 block of the original image, starting with the top left 8×8 block, and working horizontally across the page (as it will be printed) until the top rightmost 8×8 block, then the next row of 8×8 blocks (left to right) and so on until the lower row of 8×8 blocks (left to right). Each 8×8 block consists of 64 8-bit pixels for color plane 0 (representing 8 rows of 8 pixels in the order top left to bottom right) followed by 64 8-bit pixels for color plane 1 and so on for up to a maximum of 4 color planes.

If the original image is not a multiple of 8 pixels in X or Y, padding must be present (the extra pixel data will be ignored by the setting of margins).

20 8.1.2.4.3 Compressed format

25

40

If the contone data is compressed the first memory band contains JPEG headers (including tables) plus MCUs (minimum coded units). The ratio of space between the various color planes in the JPEG stream is 1:1:1:1. No subsampling is permitted. Banding can be completely arbitrary i.e there can be multiple JPEG images per band or 1 JPEG image divided over multiple bands. The break between bands is only memory alignment based.

8.1.2.4.4 Conversion of RGB to YCrCb (in RIP)

YCrCb is defined as per CCIR 601-1 [24] except that Y, Cr and Cb are normalized to occupy all 256 levels of an 8-bit binary encoding and take account of the actual hardware implementation of the inverse transform within SoPEC.

- 30 The exact color conversion computation is as follows:
 - $Y^* = (9805/32768)R + (19235/32768)G + (3728/32768)B$
 - Cr* = (16375/32768)R (13716/32768)G (2659/32768)B + 128
 - $Cb^* = -(5529/32768)R (10846/32768)G + (16375/32768)B + 128$

Y, Cr and Cb are obtained by rounding to the nearest integer. There is no need for saturation since ranges of Y*, Cr* and Cb* after rounding are [0-255], [1-255] and [1-255] respectively. *Note that full accuracy is possible with 24 bits*. See [14] for more information.

SOPEC ASIC

9 Overview

The Small Office Home Office Print Engine Controller (SoPEC) is a page rendering engine ASIC that takes compressed page images as input, and produces decompressed page images at up to 6

channels of bi-level dot data as output. The bi-level dot data is generated for the Memjet bi-lithic printhead. The dot generation process takes account of printhead construction, dead nozzles, and allows for fixative generation.

A single SoPEC can control 2 bi-lithic printheads and up to 6 color channels at 10,000 lines/sec⁵, equating to 30 pages per minute. A single SoPEC can perform full-bleed printing of A3, A4 and Letter pages. The 6 channels of colored ink are the expected maximum in a consumer SOHO, or office Bi-lithic printing environment:

- CMY, for regular color printing.
- K, for black text, line graphics and gray-scale printing.
- IR (infrared), for Netpage-enabled [5] applications.
 - F (fixative), to enable printing at high speed. Because the bi-lithic printer is capable of printing so fast, a fixative may be required to enable the ink to dry before the page touches the page already printed. Otherwise the pages may bleed on each other. In low speed printing environments the fixative may not be required.
- SoPEC is color space agnostic. Although it can accept contone data as CMYX or RGBX, where X is an optional 4th channel, it also can accept contone data in any print color space. Additionally, SoPEC provides a mechanism for arbitrary mapping of input channels to output channels, including combining dots for ink optimization, generation of channels based on any number of other channels etc. However, inputs are typically CMYK for contone input, K for the bi-level input, and the optional Netpage tag dots are typically rendered to an infra-red layer. A fixative channel is typically generated for fast printing applications.
 - SoPEC is resolution agnostic. It merely provides a mapping between input resolutions and output resolutions by means of scale factors. The expected output resolution is 1600 dpi, but SoPEC actually has no knowledge of the physical resolution of the Bi-lithic printhead.
- SoPEC is *page-length agnostic*. Successive pages are typically split into bands and downloaded into the page store as each band of information is consumed and becomes free.
 - SoPEC provides an interface for synchronization with other SoPECs. This allows simple multi-SoPEC solutions for simultaneous A3/A4/Letter duplex printing. However, SoPEC is also capable of printing only a portion of a page image. Combining synchronization functionality with partial page rendering allows multiple SoPECs to be readily combined for alternative printing requirements including simultaneous duplex printing and wide format printing.

Table 8 lists some of the features and corresponding benefits of SoPEC.

Table 8. Features and Benefits of SoPEC

30

Feature	Benefits
Optimised print architecture in	30ppm full page photographic quality color printing from a
hardware	desktop PC

⁵10,000 lines per second equates to 30 A4/Letter pages per minute at 1600 dpi

0.13micron CMOS	High speed
(>3 million transistors)	Low cost
	High functionality
900 Million dots per second	Extremely fast page generation
10,000 lines per second at 1600	0.5 A4/Letter pages per SoPEC chip per second
dpi	
1 chip drives up to 133,920	Low cost page-width printers
nozzles	
1 chip drives up to 6 color planes	99% of SoHo printers can use 1 SoPEC device
Integrated DRAM	No external memory required, leading to low cost systems
Power saving sleep mode	SoPEC can enter a power saving sleep mode to reduce
	power dissipation between print jobs
JPEG expansion	Low bandwidth from PC
	Low memory requirements in printer
Lossless bitplane expansion	High resolution text and line art with low bandwidth from PC
	(e.g. over USB)
Netpage tag expansion	Generates interactive paper
Stochastic dispersed dot dither	Optically smooth image quality
	No moire effects
Hardware compositor for 6 image	Pages composited in real-time
planes	
Dead nozzle compensation	Extends printhead life and yield
	Reduces printhead cost
Color space agnostic	Compatible with all inksets and image sources including
	RGB, CMYK, spot, CIE L*a*b*, hexachrome, YCrCbK,
	sRGB and other
Color space conversion	Higher quality / lower bandwidth
Computer interface	USB1.1 interface to host and ISI interface to ISI-Bridge chip
	thereby allowing connection to IEEE 1394, Bluetooth etc.
Cascadable in resolution	Printers of any resolution
Cascadable in color depth	Special color sets e.g. hexachrome can be used
Cascadable in image size	Printers of any width up to 16 inches
Cascadable in pages	Printers can print both sides simultaneously
Cascadable in speed	Higher speeds are possible by having each SoPEC print one
	vertical strip of the page.
Fixative channel data generation	Extremely fast ink drying without wastage
Built-in security	Revenue models are protected
Undercolor removal on dot-by-dot	Reduced ink usage
basis	

Does not require fonts for high	No font substitution or missing fonts
speed operation	
Flexible printhead configuration	Many configurations of printheads are supported by one chip type
Drives Bi-lithic printheads directly	No print driver chips required, results in lower cost
Determines dot accurate ink usage	Removes need for physical ink monitoring system in ink cartridges

9.1 PRINTING RATES

5

10

15

The required printing rate for SoPEC is 30 sheets per minute with an inter-sheet spacing of 4 cm. To achieve a 30 sheets per minute print rate, this requires:

300mm x 63 (dot/mm) / 2 sec = 105.8 µseconds per line, with no inter-sheet gap.

340mm x 63 (dot/mm) / 2 sec = 93.3 μseconds per line, with a 4 cm inter-sheet gap.

A printline for an A4 page consists of 13824 nozzles across the page [2]. At a system clock rate of 160 MHz 13824 dots of data can be generated in 86.4 µseconds. Therefore data can be generated fast enough to meet the printing speed requirement. It is necessary to deliver this print data to the print-heads.

Printheads can be made up of 5:5, 6:4, 7:3 and 8:2 inch printhead combinations [2]. Print data is transferred to both print heads in a pair simultaneously. This means the longest time to print a line is determined by the time to transfer print data to the longest print segment. There are 9744 nozzles across a 7 inch printhead. The print data is transferred to the printhead at a rate of 106 MHz (2/3 of the system clock rate) per color plane. This means that it will take 91.9 μ s to transfer a single line for a 7:3 printhead configuration. So we can meet the requirement of 30 sheets per minute printing with a 4 cm gap with a 7:3 printhead combination. There are 11160 across an 8 inch printhead. To transfer the data to the printhead at 106 MHz will take 105.3 μ s. So an 8:2 printhead combination printing with an inter-sheet gap will print slower than 30 sheets per minute.

20 9.2 SOPEC BASIC ARCHITECTURE

From the highest point of view the SoPEC device consists of 3 distinct subsystems

- CPU Subsystem
- DRAM Subsystem
- Print Engine Pipeline (PEP) Subsystem
- 25 See Figure 13 for a block level diagram of SoPEC.

9.2.1 CPU Subsystem

The CPU subsystem controls and configures all aspects of the other subsystems. It provides general support for interfacing and synchronising the external printer with the internal print engine. It also controls the low speed communication to the QA chips. The CPU subsystem contains various peripherals to aid the CPU, such as GPIO (includes motor control), interrupt controller, LSS Master and general timers. The Serial Communications Block (SCB) on the CPU subsystem provides a full speed USB1.1 interface to the host as well as an Inter SoPEC Interface (ISI) to other SoPEC devices.

9.2.2 DRAM Subsystem

The DRAM subsystem accepts requests from the CPU, Serial Communications Block (SCB) and blocks within the PEP subsystem. The DRAM subsystem (in particular the DIU) arbitrates the various requests and determines which request should win access to the DRAM. The DIU arbitrates based on configured parameters, to allow sufficient access to DRAM for all requestors. The DIU also hides the implementation specifics of the DRAM such as page size, number of banks, refresh rates etc.

9.2.3 Print Engine Pipeline (PEP) subsystem

5

10

15

20

25

30

The Print Engine Pipeline (PEP) subsystem accepts compressed pages from DRAM and renders them to bi-level dots for a given print line destined for a printhead interface that communicates directly with up to 2 segments of a bi-lithic printhead.

The first stage of the page expansion pipeline is the CDU, LBD and TE. The CDU expands the JPEG-compressed contone (typically CMYK) layer, the LBD expands the compressed bi-level layer (typically K), and the TE encodes Netpage tags for later rendering (typically in IR or K ink). The output from the first stage is a set of buffers: the CFU, SFU, and TFU. The CFU and SFU buffers are implemented in DRAM.

The second stage is the HCU, which dithers the contone layer, and composites position tags and the bi-level spot0 layer over the resulting bi-level dithered layer. A number of options exist for the way in which compositing occurs. Up to 6 channels of bi-level data are produced from this stage. Note that not all 6 channels may be present on the printhead. For example, the printhead may be CMY only, with K pushed into the CMY channels and IR ignored. Alternatively, the position tags may be printed in K if IR ink is not available (or for testing purposes).

The third stage (DNC) compensates for dead nozzles in the printhead by color redundancy and error diffusing dead nozzle data into surrounding dots.

The resultant bi-level 6 channel dot-data (typically CMYK-IRF) is buffered and written out to a set of line buffers stored in DRAM via the DWU.

Finally, the dot-data is loaded back from DRAM, and passed to the printhead interface via a dot FIFO. The dot FIFO accepts data from the LLU at the system clock rate (*pclk*), while the PHI removes data from the FIFO and sends it to the printhead at a rate of 2/3 times the system clock rate (see Section 9.1).

9.3 SOPEC BLOCK DESCRIPTION

Looking at Figure 13, the various units are described here in summary form:

Table 9. Units within SoPEC

Subsystem	Unit	Unit Name	Description
	Acronym		
DRAM	DIU	DRAM interface unit	Provides the interface for DRAM read and write
			access for the various SoPEC units, CPU and
			the SCB block. The DIU provides arbitration
			between competing units controls DRAM

43

			access.
·	DRAM	Embedded DRAM	20Mbits of embedded DRAM,
CPU	CPU	Central Processing	CPU for system configuration and control
		Unit	
	мми	Memory Management	Limits access to certain memory address areas
		Unit	in CPU user mode
	RDU	Real-time Debug Unit	Facilitates the observation of the contents of
			most of the CPU addressable registers in
			SoPEC in addition to some pseudo-registers in
			realtime.
	ТІМ	General Timer	Contains watchdog and general system timers
	LSS	Low Speed Serial	Low level controller for interfacing with the QA
		Interfaces	chips
	GPIO	General Purpose IOs	General IO controller, with built-in Motor control
			unit, LED pulse units and de-glitch circuitry
	ROM	Boot ROM	16 KBytes of System Boot ROM code
	ICU	Interrupt Controller	General Purpose interrupt controller with
		Unit	configurable priority, and masking.
	CPR	Clock, Power and	Central Unit for controlling and generating the
		Reset block	system clocks and resets and powerdown
			mechanisms
	PSS	Power Save Storage	Storage retained while system is powered down
	USB	Universal Serial Bus	USB device controller for interfacing with the
		Device	host USB.
	ISI	Inter-SoPEC Interface	ISI controller for data and control
			communication with other SoPEC's in a multi-
			SoPEC system
	SCB	Serial Communication	Contains both the USB and ISI blocks.
		Block	
Print Engine	PCU	PEP controller	Provides external CPU with the means to read
Pipeline			and write PEP Unit registers, and read and
(PEP)			write DRAM in single 32-bit chunks.
	CDU	Contone decoder unit	Expands JPEG compressed contone layer and
			writes decompressed contone to DRAM
	CFU	Contone FIFO Unit	Provides line buffering between CDU and HCU
	LBD	Lossless Bi-level	Expands compressed bi-level layer.
		Decoder	
	SFU	Spot FIFO Unit	Provides line buffering between LBD and HCU
	TE	Tag encoder	Encodes tag data into line of tag dots.

TFU	Tag FIFO Unit	Provides tag data storage between TE and HCU
HCU	Halftoner compositor	Dithers contone layer and composites the bi-
	unit	level spot 0 and position tag dots.
DNC	Dead Nozzle	Compensates for dead nozzles by color
	Compensator	redundancy and error diffusing dead nozzle
		data into surrounding dots.
DWU	Dotline Writer Unit	Writes out the 6 channels of dot data for a
		given printline to the line store DRAM
LLU	Line Loader Unit	Reads the expanded page image from line
		store, formatting the data appropriately for the
		bi-lithic printhead.
PHI	PrintHead Interface	Is responsible for sending dot data to the bi-
		lithic printheads and for providing line
		synchronization between multiple SoPECs.
		Also provides test interface to printhead such
		as temperature monitoring and Dead Nozzle
		Identification.

9.4 ADDRESSING SCHEME IN SOPEC

SoPEC must address

20 Mbit DRAM.

5

20

- PCU addressed registers in PEP.
 - CPU-subsystem addressed registers.

SoPEC has a unified address space with the CPU capable of addressing all CPU-subsystem and PCU-bus accessible registers (in PEP) and all locations in DRAM. The CPU generates byte-aligned addresses for the whole of SoPEC.

10 22 bits are sufficient to byte address the whole SoPEC address space.

9.4.1 DRAM addressing scheme

The embedded DRAM is composed of 256-bit words. However the CPU-subsystem may need to write individual bytes of DRAM. Therefore it was decided to make the DIU byte addressable. 22 bits are required to byte address 20 Mbits of DRAM.

Most blocks read or write 256-bit words of DRAM. Therefore only the top 17 bits i.e. bits 21 to 5 are required to address 256-bit word aligned locations.

The exceptions are

- CDU which can write 64-bits so only the top 19 address bits i.e. bits 21-3 are required.
- The CPU-subsystem always generates a 22-bit byte-aligned DIU address but it will send flags to the DIU indicating whether it is an 8, 16 or 32-bit write.

All DIU accesses must be within the same 256-bit aligned DRAM word.

9.4.2 PEP Unit DRAM addressing

PEP Unit configuration registers which specify DRAM locations should specify 256-bit aligned DRAM addresses i.e. using address bits 21:5. Legacy blocks from PEC1 e.g. the LBD and TE may need to specify 64-bit aligned DRAM addresses if these reused blocks DRAM addressing is difficult to modify. These 64-bit aligned addresses require address bits 21:3. However, these 64-bit aligned addresses should be programmed to start at a 256-bit DRAM word boundary.

Unlike PEC1, there are no constraints in SoPEC on data organization in DRAM except that all data structures must start on a 256-bit DRAM boundary. If data stored is not a multiple of 256-bits then the last word should be padded.

- 9.4.3 CPU subsystem bus addressed registers
- The CPU subsystem bus supports 32-bit word aligned read and write accesses with variable access timings. See section 11.4 for more details of the access protocol used on this bus. The CPU subsystem bus does not currently support byte reads and writes but this can be added at a later date if required by imported IP.
 - 9.4.4 PCU addressed registers in PEP
- The PCU only supports 32-bit register reads and writes for the PEP blocks. As the PEP blocks only occupy a subsection of the overall address map and the PCU is explicitly selected by the MMU when a PEP block is being accessed the PCU does not need to perform a decode of the higher-order address bits. See Table 11 for the PEP subsystem address map.
 - 9.5 SOPEC MEMORY MAP
- 20 9.5.1 Main memory map

5

The system wide memory map is shown in Figure 14 below. The memory map is discussed in detail in Section 11 11 Central Processing Unit (CPU).

9.5.2 CPU-bus peripherals address map

The address mapping for the peripherals attached to the CPU-bus is shown in Table 10 below. The MMU performs the decode of cpu_adr[21:12] to generate the relevant cpu_block_select signal for each block. The addressed blocks decode however many of the lower order bits of cpu_adr[11:2] are required to address all the registers within the block.

Table 10. CPU-bus peripherals address map

Block_base	Address
ROM_base	0x0000_0000
MMU_base	0x0001_0000
TIM_base	0x0001_1000
LSS_base	0x0001_2000
GPIO_base	0x0001_3000
SCB_base	0x0001_4000
ICU_base	0x0001_5000
CPR_base	0x0001_6000
DIU_base	0x0001_7000

	0x0001_8000
Reserved	0x0001_9000 to 0x0001_FFFF
PCU_base	0x0002_0000 to 0x0002_BFFF

9.5.3 PCU Mapped Registers (PEP blocks) address map

The PEP blocks are addressed via the PCU. From Figure 14, the PCU mapped registers are in the range 0x0002_0000 to 0x0002_BFFF. From Table 11 it can be seen that there are 12 sub-blocks within the PCU address space. Therefore, only four bits are necessary to address each of the sub-blocks within the PEP part of SoPEC. A further 12 bits may be used to address any configurable register within a PEP block. This gives scope for 1024 configurable registers per sub-block (the PCU mapped registers are all 32-bit addressed registers so the upper 10 bits are required to individually address them). This address will come either from the CPU or from a command stored in DRAM. The bus is assembled as follows:

10 • address[15:12] = sub-block address,

5

- address[n:2] = register address within sub-block, only the number of bits required to decode the registers within each sub-block are used,
- address[1:0] = byte address, unused as PCU mapped registers are all 32-bit addressed registers.
- So for the case of the HCU, its addresses range from 0x7000 to 0x7FFF within the PEP subsystem or from 0x0002_7000 to 0x0002_7FFF in the overall system.

Table 11. PEP blocks address map

Block_base	Address
PCU_base	0x0002_0000
CDU_base	0x0002_1000
CFU_base	0x0002_2000
LBD_base	0x0002_3000
SFU_base	0x0002_4000
TE_base	0x0002_5000
TFU_base	0x0002_6000
HCU_base	0x0002_7000
DNC_base	0x0002_8000
DWU_base	0x0002_9000
LLU_base	0x0002_A000
PHI_base	0x0002_B000 to 0x0002_BFFF

- 9.6 BUFFER MANAGEMENT IN SOPEC
- As outlined in Section 9.1, SoPEC has a requirement to print 1 side every 2 seconds i.e. 30 sides per minute.
 - 9.6.1 Page buffering

Approximately 2 Mbytes of DRAM are reserved for compressed page buffering in SoPEC. If a page is compressed to fit within 2 Mbyte then a complete page can be transferred to DRAM before printing. However, the time to transfer 2 Mbyte using USB 1.1 is approximately 2 seconds. The worst case cycle time to print a page then approaches 4 seconds. This reduces the worst-case print speed to 15 pages per minute.

9.6.2 Band buffering

5

20

The SoPEC page-expansion blocks support the notion of page banding. The page can be divided into bands and another band can be sent down to SoPEC while we are printing the current band. Therefore we can start printing once at least one band has been downloaded.

- The band size granularity should be carefully chosen to allow efficient use of the USB bandwidth and DRAM buffer space. It should be small enough to allow seamless 30 sides per minute printing but not so small as to introduce excessive CPU overhead in orchestrating the data transfer and parsing the band headers. Band-finish interrupts have been provided to notify the CPU of free buffer space. It is likely that the host PC will supervise the band transfer and buffer management instead of the SoPEC CPU.
 - If SoPEC starts printing before the complete page has been transferred to memory there is a risk of a buffer underrun occurring if subsequent bands are not transferred to SoPEC in time e.g. due to insufficient USB bandwidth caused by another USB peripheral consuming USB bandwidth. A buffer underrun occurs if a line synchronisation pulse is received before a line of data has been transferred to the printhead and causes the print job to fail at that line. If there is no risk of buffer
- underrun then printing can safely start once at least one band has been downloaded.

 If there is a risk of a buffer underrun occurring due to an interruption of compressed page data transfer, then the safest approach is to only start printing once we have loaded up the data for a complete page. This means that a worst case latency in the region of 2 seconds (with USB1.1) will
- be incurred before printing the first page. Subsequent pages will take 2 seconds to print giving us the required sustained printing rate of 30 sides per minute.
 - A Storage SoPEC (Section 7.2.5) could be added to the system to provide guaranteed bandwidth data delivery. The print system could also be constructed using an ISI-Bridge chip (Section 7.2.6) to provide guaranteed data delivery.
- The most efficient page banding strategy is likely to be determined on a per page/ print job basis and so SoPEC will support the use of bands of any size.
 - 10 SoPEC Use Cases
 - 10.1 INTRODUCTION

This chapter is intended to give an overview of a representative set of scenarios or *use cases* which SoPEC can perform. SoPEC is by no means restricted to the particular use cases described and not every SoPEC system is considered here.

In this chapter we discuss SoPEC use cases under four headings:

- 1) Normal operation use cases.
- 2) Security use cases.
- 40 3) Miscellaneous use cases.

4) Failure mode use cases.

Use cases for both single and multi-SoPEC systems are outlined.

Some tasks may be composed of a number of sub-tasks.

The realtime requirements for SoPEC software tasks are discussed in "11 Central Processing Unit (CPU)" under Section 11.3 Realtime requirements.

10.2 NORMAL OPERATION IN A SINGLE SOPEC SYSTEM WITH USB HOST CONNECTION SOPEC operation is broken up into a number of sections which are outlined below. Buffer management in a SoPEC system is normally performed by the host.

10.2.1 Powerup

5

Powerup describes SoPEC initialisation following an external reset or the watchdog timer system reset.

A typical powerup sequence is:

- 1) Execute reset sequence for complete SoPEC.
- 2) CPU boot from ROM.
- 15 3) Basic configuration of CPU peripherals, SCB and DIU. DRAM initialisation. USB Wakeup.
 - 4) Download and authentication of program (see Section 10.5.2).
 - 5) Execution of program from DRAM.
 - 6) Retrieve operating parameters from PRINTER_QA and authenticate operating parameters.
 - 7) Download and authenticate any further *datasets*.
- 20 10.2.2 USB wakeup

The CPU can put different sections of SoPEC into sleep mode by writing to registers in the CPR block (chapter 16). Normally the CPU sub-system and the DRAM will be put in sleep mode but the SCB and power-safe storage (PSS) will still be enabled.

Wakeup describes SoPEC recovery from sleep mode with the SCB and power-safe storage (PSS)

still enabled. In a single SoPEC system, wakeup can be initiated following a USB reset from the SCB.

A typical USB wakeup sequence is:

- 1) Execute reset sequence for sections of SoPEC in sleep mode.
- 2) CPU boot from ROM, if CPU-subsystem was in sleep mode.
- 30 3) Basic configuration of CPU peripherals and DIU, and DRAM initialisation, if required.
 - 4) Download and authentication of program using results in Power-Safe Storage (PSS) (see Section 10.5.2).
 - 5) Execution of program from DRAM.
 - 6) Retrieve operating parameters from PRINTER_QA and authenticate operating parameters.
- 35 7) Download and authenticate using results in PSS of any further datasets (programs).

10.2.3 Print initialization

This sequence is typically performed at the start of a print job following powerup or wakeup:

- 1) Check amount of ink remaining via QA chips.
- 2) Download static data e.g. dither matrices, dead nozzle tables from host to DRAM.

- 3) Check printhead temperature, if required, and configure printhead with firing pulse profile etc. accordingly.
- 4) Initiate printhead pre-heat sequence, if required.

10.2.4 First page download

5 Buffer management in a SoPEC system is normally performed by the host.

First page, first band download and processing:

- 1) The host communicates to the SoPEC CPU over the USB to check that DRAM space remaining is sufficient to download the first band.
- 2) The host downloads the first band (with the page header) to DRAM.
- When the complete page header has been downloaded the SoPEC CPU processes the page header, calculates PEP register commands and writes directly to PEP registers or to DRAM.
 - 4) If PEP register commands have been written to DRAM, execute PEP commands from DRAM via PCU.

Remaining bands download and processing:

- 15 1) Check DRAM space remaining is sufficient to download the next band.
 - 2) Download the next band with the band header to DRAM.
 - 3) When the complete band header has been downloaded, process the band header according to whichever band-related register updating mechanism is being used.

10.2.5 Start printing

20 1) Wait until at least one band of the first page has been downloaded.

One approach is to only start printing once we have loaded up the data for a complete page. If we start printing before the complete page has been transferred to memory we run the risk of a buffer underrun occurring because compressed page data was not transferred to SoPEC in time e.g. due to insufficient USB bandwidth caused by another USB peripheral consuming USB bandwidth.

2) Start all the PEP Units by writing to their *Go* registers, via PCU commands executed from DRAM or direct CPU writes. A rapid startup order for the PEP units is outlined in Table 12. Table 12. Typical PEP Unit startup order for printing a page.

Step#	Unit
1	DNC
2	DWU
3	нси
4	PHI
5	LLU
6	CFU, SFU, TFU
7	CDU
8	TE, LBD

30

25

3) Print ready interrupt occurs (from PHI).

- 4) Start motor control, if first page, otherwise feed the next page. This step could occur before the print ready interrupt.
- 5) Drive LEDs, monitor paper status.
- 6) Wait for page alignment via page sensor(s) GPIO interrupt.
- 5 7) CPU instructs PHI to start producing line syncs and hence commence printing, or wait for an external device to produce line syncs.
 - 8) Continue to download bands and process page and band headers for next page.

10.2.6 Next page(s) download

As for first page download, performed during printing of current page.

10 10.2.7 Between bands

When the finished band flags are asserted band related registers in the CDU, LBD, TE need to be re-programmed before the subsequent band can be printed. This can be via PCU commands from DRAM. Typically only 3-5 commands per decompression unit need to be executed. These registers can also be reprogrammed directly by the CPU or most likely by updating from shadow registers.

The finished band flag interrupts the CPU to tell the CPU that the area of memory associated with the band is now free.

10.2.8 During page print

Typically during page printing ink usage is communicated to the QA chips.

- 1) Calculate ink printed (from PHI).
- 20 2) Decrement ink remaining (via QA chips).
 - 3) Check amount of ink remaining (via QA chips). This operation may be better performed while the page is being printed rather than at the end of the page.

10.2.9 Page finish

These operations are typically performed when the page is finished:

- 25 1) Page finished interrupt occurs from PHI.
 - 2) Shutdown the PEP blocks by de-asserting their Go registers. A typical shutdown order is defined in Table 13. This will set the PEP Unit state-machines to their idle states without resetting their configuration registers.
 - 3) Communicate ink usage to QA chips, if required.
- Table 13. End of page shutdown order for PEP Units.

Step#	Unit
1	PHI (will shutdown by itself in the normal case at the end of a page)
2	DWU (shutting this down stalls the DNC and therefore the HCU and above)
3	LLU (should already be halted due to PHI at end of last line of page)
4	TE (this is the only dot supplier likely to be running, halted by the HCU)
5	CDU (this is likely to already be halted due to end of contone band)

6	CFU, SFU, TFU, LBD (order unimportant, and should already be				
	halted due to end of band)				
7	HCU, DNC (order unimportant, should already have halted)				

10.2.10 Start of next page

These operations are typically performed before printing the next page:

- 1) Re-program the PEP Units via PCU command processing from DRAM based on page header.
- 2) Go to Start printing.
- 5 10.2.11 End of document
 - 1) Stop motor control.

10.2.12 Sleep mode

The CPU can put different sections of SoPEC into sleep mode by writing to registers in the CPR block described in Section 16.

- 10 1) Instruct host PC via USB that SoPEC is about to sleep.
 - 2) Store reusable authentication results in Power-Safe Storage (PSS).
 - 3) Put SoPEC into defined sleep mode.
 - 10.3 NORMAL OPERATION IN A MULTI-SOPEC SYSTEM ISIMASTER SOPEC

In a multi-SoPEC system the host generally manages program and compressed page download to all the SoPECs. Inter-SoPEC communication is over the ISI link which will add a latency. In the case of a multi-SoPEC system with just one USB 1.1 connection, the SoPEC with the USB connection is the ISIMaster. The ISI-bridge chip is the ISIMaster in the case of an ISI-Bridge SoPEC configuration. While it is perfectly possible for an ISISlave to have a direct USB connection to the host we do not treat this scenario explicitly here to avoid possible confusion.

In a multi-SoPEC system one of the SoPECs will be the PrintMaster. This SoPEC must manage and control sensors and actuators e.g. motor control. These sensors and actuators could be distributed over all the SoPECs in the system. An ISIMaster SoPEC may also be the PrintMaster SoPEC.

In a multi-SoPEC system each printing SoPEC will generally have its own PRINTER_QA chip (or at least access to a PRINTER_QA chip that contains the SoPEC's SOPEC_id_key) to validate operating parameters and ink usage. The results of these operations may be communicated to the PrintMaster SoPEC.

In general the ISIMaster may need to be able to:

- ullet Send messages to the ISISlaves which will cause the ISISlaves to send their status to the ISIMaster.
 - Instruct the ISISlaves to perform certain operations.
 As the ISI is an insecure interface commands issued over the ISI are regarded as user mode commands. Supervisor mode code running on the SoPEC CPUs will allow or disallow these commands. The software protocol needs to be constructed with this in mind.
- The ISIMaster will initiate all communication with the ISISlaves.

 SoPEC operation is broken up into a number of sections which are outlined below.
 - 10.3.1 Powerup

Powerup describes SoPEC initialisation following an external reset or the watchdog timer system reset.

- 1) Execute reset sequence for complete SoPEC.
- 2) CPU boot from ROM.
- 5 3) Basic configuration of CPU peripherals, SCB and DIU. DRAM initialisation USB Wakeup
 - 4) SoPEC identification by activity on USB end-points 2-4 indicates it is the ISIMaster (unless the SoPEC CPU has explicitly disabled this function).
 - 5) Download and authentication of program (see Section 10.5.3).
 - 6) Execution of program from DRAM.
- 10 7) Retrieve operating parameters from PRINTER_QA and authenticate operating parameters.
 - 8) Download and authenticate any further datasets (programs).
 - 9) The initial dataset may be broadcast to all the ISISlaves.
 - 10) ISIMaster master SoPEC then waits for a short time to allow the authentication to take place on the ISISlave SoPECs.
- 15 11) Each ISISlave SoPEC is polled for the result of its program code authentication process.
 - 12) If all ISISlaves report successful authentication the OEM code module can be distributed and authenticated. OEM code will most likely reside on one SoPEC.

10.3.2 USB wakeup

The CPU can put different sections of SoPEC into sleep mode by writing to registers in the CPR

block [16]. Normally the CPU sub-system and the DRAM will be put in sleep mode but the SCB and power-safe storage (PSS) will still be enabled.

Wakeup describes SoPEC recovery from sleep mode with the SCB and power-safe storage (PSS) still enabled. For an ISIMaster SoPEC connected to the host via USB, wakeup can be initiated following a USB reset from the SCB.

- 25 A typical USB wakeup sequence is:
 - 1) Execute reset sequence for sections of SoPEC in sleep mode.
 - 2) CPU boot from ROM, if CPU-subsystem was in sleep mode.
 - 3) Basic configuration of CPU peripherals and DIU, and DRAM initialisation, if required.
- 4) SoPEC identification by activity on USB end-points 2-4 indicates it is the ISIMaster (unless the SoPEC CPU has explicitly disabled this function).
 - 5) Download and authentication of program using results in Power-Safe Storage (PSS) (see Section 10.5.3).
 - Execution of program from DRAM.
 - 7) Retrieve operating parameters from PRINTER_QA and authenticate operating parameters.
- 35 8) Download and authenticate any further *datasets* (programs) using results in Power-Safe Storage (PSS) (see Section 10.5.3).
 - 9) Following steps as per Powerup.

10.3.3 Print initialization

This sequence is typically performed at the start of a print job following powerup or wakeup:

40 1) Check amount of ink remaining via QA chips which may be present on a ISISlave SoPEC.

- 2) Download static data e.g. dither matrices, dead nozzle tables from host to DRAM.
- Check printhead temperature, if required, and configure printhead with firing pulse profile etc. accordingly. Instruct ISISlaves to also perform this operation.
- 4) Initiate printhead pre-heat sequence, if required. Instruct ISISlaves to also perform this operation

10.3.4 First page download

5

20

25

40

Buffer management in a SoPEC system is normally performed by the host.

- 1) The host communicates to the SoPEC CPU over the USB to check that DRAM space remaining is sufficient to download the first band.
- 10 2) The host downloads the first band (with the page header) to DRAM.
 - 3) When the complete page header has been downloaded the SoPEC CPU processes the page header, calculates PEP register commands and write directly to PEP registers or to DRAM.
 - 4) If PEP register commands have been written to DRAM, execute PEP commands from DRAM via PCU.
- 15 Poll ISISlaves for DRAM status and download compressed data to ISISlaves.

Remaining first page bands download and processing:

- 1) Check DRAM space remaining is sufficient to download the next band.
- 2) Download the next band with the band header to DRAM.
- When the complete band header has been downloaded, process the band header according to whichever band-related register updating mechanism is being used.

Poll ISISlaves for DRAM status and download compressed data to ISISlaves.

10.3.5 Start printing

- 1) Wait until at least one band of the first page has been downloaded.
- 2) Start all the PEP Units by writing to their *Go* registers, via PCU commands executed from DRAM or direct CPU writes, in the suggested order defined in Table .
- 3) Print ready interrupt occurs (from PHI). Poll ISISlaves until print ready interrupt.
- 4) Start motor control (which may be on an ISISlave SoPEC), if first page, otherwise feed the next page. This step could occur before the print ready interrupt.
- 5) Drive LEDS, monitor paper status (which may be on an ISISlave SoPEC).
- Wait for page alignment via page sensor(s) GPIO interrupt (which may be on an ISISlave SoPEC).
 - 7) If the LineSyncMaster is a SoPEC its CPU instructs PHI to start producing master line syncs. Otherwise wait for an external device to produce line syncs.
 - 8) Continue to download bands and process page and band headers for next page.
- 35 10.3.6 Next page(s) download

As for first page download, performed during printing of current page.

10.3.7 Between bands

When the finished band flags are asserted band related registers in the CDU, LBD and TE need to be re-programmed. This can be via PCU commands from DRAM. Typically only 3-5 commands per decompression unit need to be executed. These registers can also be reprogrammed directly by the

CPU or by updating from shadow registers. The finished band flag interrupts to the CPU, tell the CPU that the area of memory associated with the band is now free.

10.3.8 During page print

Typically during page printing ink usage is communicated to the QA chips.

- 5 1) Calculate ink printed (from PHI).
 - 2) Decrement ink remaining (via QA chips).
 - 3) Check amount of ink remaining (via QA chips). This operation may be better performed while the page is being printed rather than at the end of the page.

10.3.9 Page finish

- 10 These operations are typically performed when the page is finished:
 - 1) Page finished interrupt occurs from PHI. Poll ISISlaves for page finished interrupts.
 - Shutdown the PEP blocks by de-asserting their Go registers in the suggested order in TableThis will set the PEP Unit state-machines to their startup states.
 - 3) Communicate ink usage to QA chips, if required.
- 15 10.3.10 Start of next page

These operations are typically performed before printing the next page:

- Re-program the PEP Units via PCU command processing from DRAM based on page header.
- 2) Go to Start printing.
- 20 10.3.11 End of document
 - 1) Stop motor control. This may be on an ISISlave SoPEC.
 - 10.3.12 Sleep mode

The CPU can put different sections of SoPEC into sleep mode by writing to registers in the CPR block [16]. This may be as a result of a command from the host or as a result of a timeout.

- 25 1) Inform host PC of which parts of SoPEC system are about to sleep.
 - 2) instruct ISISlaves to enter sleep mode.
 - 3) Store reusable cryptographic results in Power-Safe Storage (PSS).
 - 4) Put ISIMaster SoPEC into defined sleep mode.
 - 10.4 NORMAL OPERATION IN A MULTI-SOPEC SYSTEM ISISLAVE SOPEC
- This section the outline typical operation of an ISISlave SoPEC in a multi-SoPEC system. The ISIMaster can be another SoPEC or an ISI-Bridge chip. The ISISlave communicates with the host either via the ISIMaster or using a direct connection such as USB. For this use case we consider only an ISISlave that does not have a direct host connection. Buffer management in a SoPEC system is normally performed by the host.
- 35 10.4.1 Powerup

Powerup describes SoPEC initialisation following an external reset or the watchdog timer system reset.

A typical powerup sequence is:

- Execute reset sequence for complete SoPEC.
- 40 2) CPU boot from ROM.

- 3) Basic configuration of CPU peripherals, SCB and DIU. DRAM initialisation.
- 4) Download and authentication of program (see Section 10.5.3).
- 5) Execution of program from DRAM.
- 6) Retrieve operating parameters from PRINTER_QA and authenticate operating parameters.
- 5 7) SoPEC identification by sampling GPIO pins to determine ISIId. Communicate ISIId to
 - 8) Download and authenticate any further datasets.

10.4.2 ISI wakeup

The CPU can put different sections of SoPEC into sleep mode by writing to registers in the CPR

10 block [16]. Normally the CPU sub-system and the DRAM will be put in sleep mode but the SCB and power-safe storage (PSS) will still be enabled.

Wakeup describes SoPEC recovery from sleep mode with the SCB and power-safe storage (PSS) still enabled. In an ISISlave SoPEC, wakeup can be initiated following an ISI reset from the SCB. A typical ISI wakeup sequence is:

- 15 1) Execute reset sequence for sections of SoPEC in sleep mode.
 - 2) CPU boot from ROM, if CPU-subsystem was in sleep mode.
 - 3) Basic configuration of CPU peripherals and DIU, and DRAM initialisation, if required.
 - 4) Download and authentication of program using results in Power-Safe Storage (PSS) (see Section 10.5.3).
- 20 5) Execution of program from DRAM.
 - 6) Retrieve operating parameters from PRINTER_QA and authenticate operating parameters.
 - SoPEC identification by sampling GPIO pins to determine ISIId. Communicate ISIId to ISIMaster.
 - 8) Download and authenticate any further datasets.
- 25 10.4.3 Print initialization

30

This sequence is typically performed at the start of a print job following powerup or wakeup:

- 1) Check amount of ink remaining via QA chips.
- 2) Download static data e.g. dither matrices, dead nozzle tables from ISI to DRAM.
- 3) Check printhead temperature, if required, and configure printhead with firing pulse profile etc. accordingly.
- 4) Initiate printhead pre-heat sequence, if required.

10.4.4 First page download

Buffer management in a SoPEC system is normally performed by the host via the ISI.

- 1) Check DRAM space remaining is sufficient to download the first band.
- 35 2) The host downloads the first band (with the page header) to DRAM via the ISI.
 - When the complete page header has been downloaded, process the page header, calculate PEP register commands and write directly to PEP registers or to DRAM.
 - 4) If PEP register commands have been written to DRAM, execute PEP commands from DRAM via PCU.
- 40 Remaining first page bands download and processing:

- 1) Check DRAM space remaining is sufficient to download the next band.
- 2) The host downloads the first band (with the page header) to DRAM via the ISI.
- 3) When the complete band header has been downloaded, process the band header according to whichever band-related register updating mechanism is being used.

5 10.4.5 Start printing

- 1) Wait until at least one band of the first page has been downloaded.
- 2) Start all the PEP Units by writing to their *Go* registers, via PCU commands executed from DRAM or direct CPU writes, in the order defined in Table .
- 3) Print ready interrupt occurs (from PHI). Communicate to PrintMaster via ISI.
- Start motor control, if attached to this ISISlave, when requested by PrintMaster, if first page, otherwise feed next page. This step could occur before the print ready interrupt
 - 5) Drive LEDS, monitor paper status, if on this ISISlave SoPEC, when requested by PrintMaster
 - 6) Wait for page alignment via page sensor(s) GPIO interrupt, if on this ISISlave SoPEC, and send to PrintMaster.
- 15 7) Wait for line sync and commence printing.
 - 8) Continue to download bands and process page and band headers for next page.

10.4.6 Next page(s) download

As for first band download, performed during printing of current page.

10.4.7 Between bands

- When the finished band flags are asserted band related registers in the CDU, LBD and TE need to be re-programmed. This can be via PCU commands from DRAM. Typically only 3-5 commands per decompression unit need to be executed. These registers can also be reprogrammed directly by the CPU or by updating from shadow registers. The finished band flag interrupts to the CPU tell the CPU that the area of memory associated with the band is now free.
- 25 10.4.8 During page print

Typically during page printing ink usage is communicated to the QA chips.

- 1) Calculate ink printed (from PHI).
- 2) Decrement ink remaining (via QA chips).
- Check amount of ink remaining (via QA chips). This operation may be better performed while
 the page is being printed rather than at the end of the page.

10.4.9 Page finish

These operations are typically performed when the page is finished:

- 1) Page finished interrupt occurs from PHI. Communicate page finished interrupt to PrintMaster.
- 2) Shutdown the PEP blocks by de-asserting their Go registers in the suggested order in Table 35 . This will set the PEP Unit state-machines to their startup states.
 - 3) Communicate ink usage to QA chips, if required.

10.4.10 Start of next page

40

These operations are typically performed before printing the next page:

 Re-program the PEP Units via PCU command processing from DRAM based on page header. Go to Start printing.

10.4.11 End of document

Stop motor control, if attached to this ISISlave, when requested by PrintMaster.

10.4.12 Powerdown

- 5 In this mode SoPEC is no longer powered.
 - 1) Powerdown ISISlave SoPEC when instructed by ISIMaster.

10.4.13 Sleep

10

20

35

The CPU can put different sections of SoPEC into sleep mode by writing to registers in the CPR block [16]. This may be as a result of a command from the host or ISIMaster or as a result of a timeout.

- 1) Store reusable cryptographic results in Power-Safe Storage (PSS).
- 2) Put SoPEC into defined sleep mode.
- 10.5 SECURITY USE CASES

Please see the 'SoPEC Security Overview' [9] document for a more complete description of SoPEC security issues. The SoPEC boot operation is described in the ROM chapter of the SoPEC hardware design specification, Section 17.2.

10.5.1 Communication with the QA chips

Communication between SoPEC and the QA chips (i.e. INK_QA and PRINTER_QA) will take place on at least a per power cycle and per page basis. Communication with the QA chips has three principal purposes: validating the presence of genuine QA chips (i.e the printer is using approved consumables), validation of the amount of ink remaining in the cartridge and authenticating the operating parameters for the printer. After each page has been printed, SoPEC is expected to communicate the number of dots fired per ink plane to the QA chipset. SoPEC may also initiate decoy communications with the QA chips from time to time.

25 Process:

• When validating ink consumption SoPEC is expected to principally act as a conduit between the PRINTER_QA and INK_QA chips and to take certain actions (basically enable or disable printing and report status to host PC) based on the result. The communication channels are insecure but all traffic is signed to guarantee authenticity.

30 Known Weaknesses

- All communication to the QA chips is over the LSS interfaces using a serial communication protocol. This is open to observation and so the communication protocol could be reverse engineered. In this case both the PRINTER_QA and INK_QA chips could be replaced by impostor devices (e.g. a single FPGA) that successfully emulated the communication protocol. As this would require physical modification of each printer this is considered to be an acceptably low risk. Any messages that are not signed by one of the symmetric keys (such as the SoPEC_id_key) could be reverse engineered. The imposter device must also have access to the appropriate keys to crack the system.
- If the secret keys in the QA chips are exposed or cracked then the system, or parts of it, is compromised.

Assumptions:

- [1] The QA chips are not involved in the authentication of downloaded SoPEC code
- [2] The QA chip in the ink cartridge (INK_QA) does not directly affect the operation of the cartridge in any way i.e. it does not inhibit the flow of ink etc.
- 5 [3] The INK_QA and PRINTER_QA chips are identical in their virgin state. They only become a INK_QA or PRINTER_QA after their FlashROM has been programmed.
 - 10.5.2 Authentication of downloaded code in a single SoPEC system

Process:

10

30

40

- 1) SoPEC identification by activity on USB end-points 2-4 indicates it is the ISIMaster (unless the SoPEC CPU has explicitly disabled this function).
- 2) The program is downloaded to the embedded DRAM.
- 3) The CPU calculates a SHA-1 hash digest of the downloaded program.
- 4) The *ResetSrc* register in the CPR block is read to determine whether or not a power-on reset occurred.
- 15 5) If a power-on reset occurred the signature of the downloaded code (which needs to be in a known location such as the first or last N bytes of the downloaded code) is decrypted using the Silverbrook public boot0key stored in ROM. This decrypted signature is the expected SHA-1 hash of the accompanying program. The encryption algorithm is likely to be a public key algorithm such as RSA. If a power-on reset did not occur then the expected SHA-1 hash is retrieved from the PSS and the compute intensive decryption is not required.
 - 6) The calculated and expected hash values are compared and if they match then the programs authenticity has been verified.
 - 7) If the hash values do not match then the host PC is notified of the failure and the SoPEC will await a new program download.
- 25 8) If the hash values match then the CPU starts executing the downloaded program.
 - 9) If, as is very likely, the downloaded program wishes to download subsequent programs (such as OEM code) it is responsible for ensuring the authenticity of everything it downloads. The downloaded program may contain public keys that are used to authenticate subsequent downloads, thus forming a hierarchy of authentication. The SoPEC ROM does not control these authentications it is solely concerned with verifying that the first program downloaded has come from a trusted source.
 - 10) At some subsequent point OEM code starts executing. The Silverbrook supervisor code acts as an O/S to the OEM user mode code. The OEM code must access most SoPEC functionality via system calls to the Silverbrook code.
- The OEM code is expected to perform some simple 'turn on the lights' tasks after which the host PC is informed that the printer is ready to print and the *Start Printing* use case comes into play.

Known Weaknesses:

 If the Silverbrook private boot0key is exposed or cracked then the system is seriously compromised. A ROM mask change would be required to reprogram the boot0key. 10.5.3 Authentication of downloaded code in a multi-SoPEC system

10.5.3.1 ISIMaster SoPEC Process:

- 1) SoPEC identification by activity on USB end-points 2-4 indicates it is the ISIMaster.
- 2) The SCB is configured to broadcast the data received from the host PC.
- 5 3) The program is downloaded to the embedded DRAM and broadcasted to all ISISlave SoPECs over the ISI.
 - 4) The CPU calculates a SHA-1 hash digest of the downloaded program.
 - 5) The *ResetSrc* register in the CPR block is read to determine whether or not a power-on reset occurred.
- 10 6) If a power-on reset occurred the signature of the downloaded code (which needs to be in a known location such as the first or last N bytes of the downloaded code) is decrypted using the Silverbrook public boot0key stored in ROM. This decrypted signature is the expected SHA-1 hash of the accompanying program. The encryption algorithm is likely to be a public key algorithm such as RSA. If a power-on reset did not occur then the expected SHA-1 hash is retrieved from the PSS and the compute intensive decryption is not required.
 - 7) The calculated and expected hash values are compared and if they match then the programs authenticity has been verified.
 - 8) If the hash values do not match then the host PC is notified of the failure and the SoPEC will await a new program download.
- 20 9) If the hash values match then the CPU starts executing the downloaded program.
 - 10) It is likely that the downloaded program will poll each ISISlave SoPEC for the result of its authentication process and to determine the number of slaves present and their ISIIds.
 - 11) If any ISISlave SoPEC reports a failed authentication then the ISIMaster communicates this to the host PC and the SoPEC will await a new program download.
- 25 12) If all ISISlaves report successful authentication then the downloaded program is responsible for the downloading, authentication and distribution of subsequent programs within the multi-SoPEC system.
 - 13) At some subsequent point OEM code starts executing. The Silverbrook supervisor code acts as an O/S to the OEM user mode code. The OEM code must access most SoPEC functionality via system calls to the Silverbrook code.
 - 14) The OEM code is expected to perform some simple 'turn on the lights' tasks after which the master SoPEC determines that all SoPECs are ready to print. The host PC is informed that the printer is ready to print and the *Start Printing* use case comes into play.

35 10.5.3.2 ISISlave SoPEC Process:

30

- When the CPU comes out of reset the SCB will be in slave mode, and the SCB is already configured to receive data from both the ISI and USB.
- 2) The program is downloaded (via ISI or USB) to embedded DRAM.
- 3) The CPU calculates a SHA-1 hash digest of the downloaded program.

- 4) The *ResetSrc* register in the CPR block is read to determine whether or not a power-on reset occurred.
- 5) If a power-on reset occurred the signature of the downloaded code (which needs to be in a known location such as the first or last N bytes of the downloaded code) is decrypted using the Silverbrook public boot0key stored in ROM. This decrypted signature is the expected SHA-1 hash of the accompanying program. The encryption algorithm is likely to be a public key algorithm such as RSA. If a power-on reset did not occur then the expected SHA-1 hash is retrieved from the PSS and the compute intensive decryption is not required.
- The calculated and expected hash values are compared and if they match then the programsauthenticity has been verified.
 - 7) If the hash values do not match, then the ISISlave device will await a new program again
 - 8) If the hash values match then the CPU starts executing the downloaded program.
 - 9) It is likely that the downloaded program will communicate the result of its authentication process to the ISIMaster. The downloaded program is responsible for determining the SoPECs ISIId, receiving and authenticating any subsequent programs.
 - 10) At some subsequent point OEM code starts executing. The Silverbrook supervisor code acts as an O/S to the OEM user mode code. The OEM code must access most SoPEC functionality via system calls to the Silverbrook code.
- 11) The OEM code is expected to perform some simple 'turn on the lights' tasks after which the master SoPEC is informed that this slave is ready to print. The *Start Printing* use case then comes into play.

Known Weaknesses

5

15

- If the Silverbrook private boot0key is exposed or cracked then the system is seriously compromised.
- ISI is an open interface i.e. messages sent over the ISI are in the clear. The communication channels are insecure but all traffic is signed to guarantee authenticity. As all communication over the ISI is controlled by Supervisor code on both the ISIMaster and ISISlave then this also provides some protection against software attacks.
 - 10.5.4 Authentication and upgrade of operating parameters for a printer
- The SoPEC IC will be used in a range of printers with different capabilities (e.g. A3/A4 printing, printing speed, resolution etc.). It is expected that some printers will also have a software upgrade capability which would allow a user to purchase a license that enables an upgrade in their printer's capabilities (such as print speed). To facilitate this it must be possible to securely store the operating parameters in the PRINTER_QA chip, to securely communicate these parameters to the SoPEC and to securely reprogram the parameters in the event of an upgrade. Note that each printing SoPEC (as opposed to a SoPEC that is only used for the storage of data) will have its own PRINTER_QA chip (or at least access to a PRINTER_QA that contains the SoPEC's SoPEC_id_key). Therefore both ISIMaster and ISISlave SoPECs will need to authenticate operating parameters.
- 40 Process:

- 1) Program code is downloaded and authenticated as described in sections 10.5.2 and 10.5.3 above.
- 2) The program code has a function to create the SoPEC_id_key from the unique SoPEC_id that was programmed when the SoPEC was manufactured.
- The SoPEC retrieves the signed operating parameters from its PRINTER_QA chip. The PRINTER_QA chip uses the SoPEC_id_key (which is stored as part of the pairing process executed during printhead assembly manufacture & test) to sign the operating parameters which are appended with a random number to thwart replay attacks.
- 4) The SoPEC checks the signature of the operating parameters using its SoPEC_id_key. If this signature authentication process is successful then the operating parameters are considered valid and the overall boot process continues. If not the error is reported to the host PC.
 - 5) Operating parameters may also be set or upgraded using a second key, the PrintEngineLicense_key, which is stored on the PRINTER_QA and used to authenticate the change in operating parameters.

15 Known Weaknesses:

20

- It may be possible to retrieve the unique SoPEC_id by placing the SoPEC in test mode and scanning it out. It is certainly possible to obtain it by reverse engineering the device. Either way the SoPEC_id (and by extension the SoPEC_id_key) so obtained is valid only for that specific SoPEC and so printers may only be compromised one at a time by parties with the appropriate specialised equipment. Furthermore even if the SoPEC_id is compromised, the other keys in the system, which protect the authentication of consumables and of program code, are unaffected.
- 10.6 MISCELLANEOUS USE CASES

There are many miscellaneous use cases such as the following examples. Software running on the SoPEC CPU or host will decide on what actions to take in these scenarios.

- 10.6.1 Disconnect / Re-connect of QA chips.
- 1) Disconnect of a QA chip between documents or if ink runs out mid-document.
- Re-connect of a QA chip once authenticated e.g. ink cartridge replacement should allow the system to resume and print the next document
- 30 10.6.2 Page arrives before print ready interrupt.
 - 1) Engage clutch to stop paper until print ready interrupt occurs.
 - 10.6.3 Dead-nozzle table upgrade

This sequence is typically performed when dead nozzle information needs to be updated by performing a printhead dead nozzle test.

- 35 1) Run printhead nozzle test sequence
 - 2) Either host or SoPEC CPU converts dead nozzle information into dead nozzle table.
 - Store dead nozzle table on host.
 - 4) Write dead nozzle table to SoPEC DRAM.
 - 10.7 FAILURE MODE USE CASES
- 40 10.7.1 System errors and security violations

System errors and security violations are reported to the SoPEC CPU and host. Software running on the SoPEC CPU or host will then decide what actions to take.

Silverbrook code authentication failure.

- 1) Notify host PC of authentication failure.
- 5 2) Abort print run.

OEM code authentication failure.

- Notify host PC of authentication failure.
- 2) Abort print run.

Invalid QA chip(s).

- 10 1) Report to host PC.
 - 2) Abort print run.

MMU security violation interrupt.

- 1) This is handled by exception handler.
- 2) Report to host PC
- 15 3) Abort print run.

Invalid address interrupt from PCU.

- 1) This is handled by exception handler.
- 2) Report to host PC.
- 3) Abort print run.
- 20 Watchdog timer interrupt.
 - 1) This is handled by exception handler.
 - 2) Report to host PC.
 - 3) Abort print run.

Host PC does not acknowledge message that SoPEC is about to power down.

25 1) Power down anyway.

10.7.2 Printing errors

Printing errors are reported to the SoPEC CPU and host. Software running on the host or SoPEC CPU will then decide what actions to take.

Insufficient space available in SoPEC compressed band-store to download a band.

30 1) Report to the host PC.

Insufficient ink to print.

1) Report to host PC.

Page not downloaded in time while printing.

- 1) Buffer underrun interrupt will occur.
- 35 2) Report to host PC and abort print run.

JPEG decoder error interrupt.

1) Report to host PC.

CPU SUBSYSTEM

40 11 Central Processing Unit (CPU)

11.1 OVERVIEW

The CPU block consists of the CPU core, MMU, cache and associated logic. The principal tasks for the program running on the CPU to fulfill in the system are:

Communications:

- Control the flow of data from the USB interface to the DRAM and ISI
 - Communication with the host via USB or ISI
 - Running the USB device driver

PEP Subsystem Control:

- Page and band header processing (may possibly be performed on host PC)
- Configure printing options on a per band, per page, per job or per power cycle basis
 - Initiate page printing operation in the PEP subsystem
 - Retrieve dead nozzle information from the printhead interface (PHI) and forward to the host
 PC
 - Select the appropriate firing pulse profile from a set of predefined profiles based on the printhead characteristics
 - Retrieve printhead temperature via the PHI

Security:

- Authenticate downloaded program code
- Authenticate printer operating parameters
- Authenticate consumables via the PRINTER_QA and INK_QA chips
 - Monitor ink usage
 - Isolation of OEM code from direct access to the system resources

Other:

- Drive the printer motors using the GPIO pins
- Monitoring the status of the printer (paper jam, tray empty etc.)
 - Driving front panel LEDs
 - Perform post-boot initialisation of the SoPEC device
 - Memory management (likely to be in conjunction with the host PC)
 - Miscellaneous housekeeping tasks

30

35

15

To control the Print Engine Pipeline the CPU is required to provide a level of performance at least equivalent to a 16-bit Hitachi H8-3664 microcontroller running at 16 MHz. An as yet undetermined amount of additional CPU performance is needed to perform the other tasks, as well as to provide the potential for such activity as Netpage page assembly and processing, RIPing etc. The extra performance required is dominated by the signature verification task and the SCB (including the USB) management task. An operating system is not required at present. A number of CPU cores have been evaluated and the LEON P1754 is considered to be the most appropriate solution. A diagram of the CPU block is shown in Figure 15 below.

11.2 DEFINITIONS OF I/OS

40 Table 14. CPU Subsystem I/Os

Port name	Pins	1/0	Description
Clocks and Resets	1	<u> </u>	
prst_n	1	ln	Global reset. Synchronous to pclk, active low.
Pclk	1	ln	Global clock
CPU to DIU DRAM interface		l,	<u> </u>
cpu_adr[21:2]	20	Out	Address bus for both DRAM and peripheral
		į	access
cpu_dataout[31:0]	32	Out	Data out to both DRAM and peripheral devices.
			This should be driven at the same time as the
	:		cpu_adr and request signals.
dram_cpu_data[255:0]	256	ln	Read data from the DRAM
cpu_diu_rreq	1	Out	Read request to the DIU DRAM
diu_cpu_rack	1	ln	Acknowledge from DIU that read request has
			been accepted.
diu_cpu_rvalid	1	ln	Signal from DIU telling SoPEC Unit that valid read
			data is on the <i>dram_cpu_data</i> bus
cpu_diu_wdatavalid	1	Out	Signal from the CPU to the DIU indicating that the
			data currently on the cpu_diu_wdata bus is valid
			and should be committed to the DIU posted write
			buffer
diu_cpu_write_rdy	1	In	Signal from the DIU indicating that the posted
			write buffer is empty
cpu_diu_wdadr[21:4]	18	Out	Write address bus to the DIU
cpu_diu_wdata[127:0]	128	Out	Write data bus to the DIU
cpu_diu_wmask[15:0]	16	Out	Write mask for the <i>cpu_diu_wdata</i> bus. Each bit
			corresponds to a byte of the 128-bit
			cpu_diu_wdata bus.
CPU to peripheral blocks	•	•	
cpu_rwn	1	Out	Common read/not-write signal from the CPU
cpu_acode[1:0]	2	Out	CPU access code signals.
			cpu_acode[0] - Program (0) / Data (1) access
			cpu_acode[1] - User (0) / Supervisor (1) access
cpu_cpr_sel	1	Out	CPR block select.
cpr_cpu_rdy	1	In	Ready signal to the CPU. When cpr_cpu_rdy is
			high it indicates the last cycle of the access. For a
			write cycle this means cpu_dataout has been
			registered by the CPR block and for a read cycle
			this means the data on cpr_cpu_data is valid.
cpr_cpu_berr	1	ln	CPR bus error signal to the CPU.

cpr_cpu_data[31:0]	32	ln	Read data bus from the CPR block
cpu_gpio_sel	1	Out	GPIO block select.
gpio_cpu_rdy	1	ln	GPIO ready signal to the CPU.
gpio_cpu_berr	1	ln	GPIO bus error signal to the CPU.
gpio_cpu_data[31:0]	32	ln	Read data bus from the GPIO block
cpu_icu_sel	1	Out	ICU block select.
icu_cpu_rdy	1	ln	ICU ready signal to the CPU.
icu_cpu_berr	1	ln	ICU bus error signal to the CPU.
icu_cpu_data[31:0]	32	ln	Read data bus from the ICU block
cpu_lss_sel	1	Out	LSS block select.
lss_cpu_rdy	1	ln	LSS ready signal to the CPU.
lss_cpu_berr	1	ln	LSS bus error signal to the CPU.
lss_cpu_data[31:0]	32	ln	Read data bus from the LSS block
cpu_pcu_sel	1	Out	PCU block select.
pcu_cpu_rdy	1	ln	PCU ready signal to the CPU.
pcu_cpu_berr	1	ln	PCU bus error signal to the CPU.
pcu_cpu_data[31:0]	32	ln	Read data bus from the PCU block
cpu_scb_sel	1	Out	SCB block select.
scb_cpu_rdy	1	ln	SCB ready signal to the CPU.
scb_cpu_berr	1	ln	SCB bus error signal to the CPU.
scb_cpu_data[31:0]	32	ln	Read data bus from the SCB block
cpu_tim_sel	1	Out	Timers block select.
tim_cpu_rdy	1	ln	Timers block ready signal to the CPU.
tim_cpu_berr	1	ln	Timers bus error signal to the CPU.
tim_cpu_data[31:0]	32	ln	Read data bus from the Timers block
cpu_rom_sel	1	Out	ROM block select.
rom_cpu_rdy	1	ln	ROM block ready signal to the CPU.
rom_cpu_berr	1	ln	ROM bus error signal to the CPU.
rom_cpu_data[31:0]	32	ln	Read data bus from the ROM block
cpu_pss_sel	1	Out	PSS block select.
pss_cpu_rdy	1	ln	PSS block ready signal to the CPU.
pss_cpu_berr	1	In	PSS bus error signal to the CPU.
pss_cpu_data[31:0]	32	ln	Read data bus from the PSS block
cpu_diu_sel	1	Out	DIU register block select.
diu_cpu_rdy	1	ln	DIU register block ready signal to the CPU.
diu_cpu_berr	1	ln	DIU bus error signal to the CPU.
diu_cpu_data[31:0]	32	in .	Read data bus from the DIU block
Interrupt signals			

icu_cpu_ilevel[3:0]	3	ln	An interrupt is asserted by driving the appropriate
			priority level on <i>icu_cpu_ilevel</i> . These signals
	- 1		must remain asserted until the CPU executes an
			interrupt acknowledge cycle.
	3	Out	Indicates the level of the interrupt the CPU is
			acknowledging when <i>cpu_iack</i> is high
cpu_iack	1	Out	Interrupt acknowledge signal. The exact timing
			depends on the CPU core implementation
Debug signals			
diu_cpu_debug_valid	1	In	Signal indicating the data on the diu_cpu_data
			bus is valid debug data.
tim_cpu_debug_valid	1	In	Signal indicating the data on the tim_cpu_data
			bus is valid debug data.
scb_cpu_debug_valid	1	ln	Signal indicating the data on the scb_cpu_data
			bus is valid debug data.
pcu_cpu_debug_valid	1	ln	Signal indicating the data on the pcu_cpu_data
		:	bus is valid debug data.
lss_cpu_debug_valid	1	ln	Signal indicating the data on the Iss_cpu_data bus
			is valid debug data.
icu_cpu_debug_valid	1	ln	Signal indicating the data on the icu_cpu_data bus
			is valid debug data.
gpio_cpu_debug_valid	1	In	Signal indicating the data on the gpio_cpu_data
			bus is valid debug data.
cpr_cpu_debug_valid	1	ln	Signal indicating the data on the cpr_cpu_data
			bus is valid debug data.
debug_data_out	32	Out	Output debug data to be muxed on to the GPIO &
			PHI pins
debug_data_valid	1	Out	Debug valid signal indicating the validity of the
			data on debug_data_out. This signal is used in all
			debug configurations
debug_cntrl	33	Out	Control signal for each PHI bound debug data line
			indicating whether or not the debug data should
			be selected by the pin mux
11.2 PEALTIME DECLIE			

11.3 REALTIME REQUIREMENTS

The SoPEC realtime requirements have yet to be fully determined but they may be split into three categories: hard, firm and soft

11.3.1 Hard realtime requirements

Hard requirements are tasks that must be completed before a certain deadline or failure to do so will result in an error perceptible to the user (printing stops or functions incorrectly). There are three hard realtime tasks:

- Motor control: The motors which feed the paper through the printer at a constant speed during printing are driven directly by the SoPEC device. Four periodic signals with different phase relationships need to be generated to ensure the paper travels smoothly through the printer. The generation of these signals is handled by the GPIO hardware (see section 13.2 for more details) but the CPU is responsible for enabling these signals (i.e. to start or stop the motors) and coordinating the movement of the paper with the printing operation of the printhead.
 - Buffer management: Data enters the SoPEC via the SCB at an uneven rate and is consumed
 by the PEP subsystem at a different rate. The CPU is responsible for managing the DRAM
 buffers to ensure that neither overrun nor underrun occur. This buffer management is likely to
 be performed under the direction of the host.
- 15 Band processing: In certain cases PEP registers may need to be updated between bands. As the timing requirements are most likely too stringent to be met by direct CPU writes to the PCU a more likely scenario is that a set of shadow registers will programmed in the compressed page units before the current band is finished, copied to band related registers by the finished band signals and the processing of the next band will continue immediately. 20 An alternative solution is that the CPU will construct a DRAM based set of commands (see section 21.8.5 for more details) that can be executed by the PCU. The task for the CPU here is to parse the band headers stored in DRAM and generate a DRAM based set of commands for the next number of bands. The location of the DRAM based set of commands must then be written to the PCU before the current band has been processed by the PEP subsystem. It 25 is also conceivable (but currently considered unlikely) that the host PC could create the DRAM based commands. In this case the CPU will only be required to point the PCU to the correct location in DRAM to execute commands from.

11.3.2 Firm requirements

5

10

30

35

Firm requirements are tasks that should be completed by a certain time or failure to do so will result in a degradation of performance but not an error. The majority of the CPU tasks for SoPEC fall into this category including all interactions with the QA chips, program authentication, page feeding, configuring PEP registers for a page or job, determining the firing pulse profile, communication of printer status to the host over the USB and the monitoring of ink usage. The authentication of downloaded programs and messages will be the most compute intensive operation the CPU will be required to perform. Initial investigations indicate that the LEON processor, running at 160 MHz, will easily perform three authentications in under a second.

Table 15. Expected firm requirements

Requirement	Duration
Power-on to start of printing first page [USB and slave SoPEC	~ 8 secs ??

enumeration, 3 or more RSA signature verifications, code and	
compressed page data download and chip initialisation]	
Wake-up from sleep mode to start printing [3 or more SHA-1 / RSA operations, code and compressed page data download and chip re-	~ 2 secs
initialisation	
Authenticate ink usage in the printer	~ 0.5 secs
Determining firing pulse profile	~ 0.1 secs
Page feeding, gap between pages	OEM dependent
Communication of printer status to host PC	~ 10 ms
Configuring PEP registers	??

11.3.3 Soft requirements

Soft requirements are tasks that need to be done but there are only light time constraints on when they need to be done. These tasks are performed by the CPU when there are no pending higher priority tasks. As the SoPEC CPU is expected to be lightly loaded these tasks will mostly be executed soon after they are scheduled.

11.4 Bus Protocols

As can be seen from Figure 15 above there are different buses in the CPU block and different protocols are used for each bus. There are three buses in operation:

10 11.4.1 AHB bus

5

25

30

The LEON CPU core uses an AMBA2.0 AHB bus to communicate with memory and peripherals (usually via an APB bridge). See the AMBA specification [38], section 5 of the LEON users manual [37] and section 11.6.6.1 of this document for more details.

11.4.2 CPU to DIU bus

This bus conforms to the DIU bus protocol described in Section 20.14.8. Note that the address bus used for DIU reads (i.e. $cpu_adr(21:2)$) is also that used for CPU subsystem with bus accesses while the write address bus (cpu_diu_wadr) and the read and write data buses ($dram_cpu_data$ and cpu_diu_wdata) are private buses between the CPU and the DIU. The effective bus width differs between a read (256 bits) and a write (128 bits). As certain CPU instructions may require byte write access this will need to be supported by both the DRAM write buffer (in the AHB bridge) and the DIU. See section 11.6.6.1 for more details.

11.4.3 CPU Subsystem Bus

For access to the on-chip peripherals a simple bus protocol is used. The MMU must first determine which particular block is being addressed (and that the access is a valid one) so that the appropriate block select signal can be generated. During a write access CPU write data is driven out with the address and block select signals in the first cycle of an access. The addressed slave peripheral responds by asserting its ready signal indicating that it has registered the write data and the access can complete. The write data bus is common to all peripherals and is also used for CPU writes to the embedded DRAM. A read access is initiated by driving the address and select signals during the first cycle of an access. The addressed slave responds by placing the read data on its

bus and asserting its ready signal to indicate to the CPU that the read data is valid. Each block has a separate point-to-point data bus for read accesses to avoid the need for a tri-stateable bus. All peripheral accesses are 32-bit (Programming note: *char* or *short* C types should not be used to access peripheral registers). The use of the ready signal allows the accesses to be of variable length. In most cases accesses will complete in two cycles but three or four (or more) cycles accesses are likely for PEP blocks or IP blocks with a different native bus interface. All PEP blocks are accessed via the PCU which acts as a bridge. The PCU bus uses a similar protocol to the CPU subsystem bus but with the PCU as the bus master.

The duration of accesses to the PEP blocks is influenced by whether or not the PCU is executing commands from DRAM. As these commands are essentially register writes the CPU access will need to wait until the PCU bus becomes available when a register access has been completed. This could lead to the CPU being stalled for up to 4 cycles if it attempts to access PEP blocks while the PCU is executing a command. The size and probability of this penalty is sufficiently small to have any significant impact on performance.

- In order to support user mode (i.e. OEM code) access to certain peripherals the CPU subsystem bus propagates the CPU function code signals (cpu_acode[1:0]). These signals indicate the type of address space (i.e. User/Supervisor and Program/Data) being accessed by the CPU for each access. Each peripheral must determine whether or not the CPU is in the correct mode to be granted access to its registers and in some cases (e.g. Timers and GPIO blocks) different access permissions can apply to different registers within the block. If the CPU is not in the correct mode then the violation is flagged by asserting the block's bus error signal (block_cpu_berr) with the same timing as its ready signal (block_cpu_rdy) which remains deasserted. When this occurs invalid read accesses should return 0 and write accesses should have no effect.
- Figure 16 shows two examples of the peripheral bus protocol in action. A write to the LSS block
 from code running in supervisor mode is successfully completed. This is immediately followed by a
 read from a PEP block via the PCU from code running in user mode. As this type of access is not
 permitted the access is terminated with a bus error. The bus error exception processing then starts
 directly after this no further accesses to the peripheral should be required as the exception handler
 should be located in the DRAM.
- Each peripheral acts as a slave on the CPU subsystem bus and its behavior is described by the state machine in section 11.4.3.1
 - 11.4.3.1 CPU subsystem bus slave state machine

5

10

35

40

CPU subsystem bus slave operation is described by the state machine in Figure 17. This state machine will be implemented in each CPU subsystem bus slave. The only new signals mentioned here are the *valid_access* and *reg_available* signals. The *valid_access* is determined by comparing the *cpu_acode* value with the block or register (in the case of a block that allow user access on a per register basis such as the GPIO block) access permissions and asserting *valid_access* if the permissions agree with the CPU mode. The *reg_available* signal is only required in the PCU or in blocks that are not capable of two-cycle access (e.g. blocks containing imported IP with different bus protocols). In these blocks the *reg_available* signal is an internal signal used to insert wait

states (by delaying the assertion of *block_cpu_rdy*) until the CPU bus slave interface can gain access to the register.

When reading from a register that is less than 32 bits wide the CPU subsystems bus slave should return zeroes on the unused upper bits of the *block_cpu_data* bus.

To support debug mode the contents of the register selected for debug observation, *debug_reg*, are always output on the *block_cpu_data* bus whenever a read access is not taking place. See section 11.8 for more details of debug operation.

11.5 LEON CPU

20

25

35

The LEON processor is an open-source implementation of the IEEE-1754 standard (SPARC V8)

instruction set. LEON is available from and actively supported by Gaisler Research (www.gaisler.com).

The following features of the LEON-2 processor will be utilised on SoPEC:

- IEEE-1754 (SPARC V8) compatible integer unit with 5-stage pipeline
- Separate instruction and data cache (Harvard architecture). 1 kbyte direct mapped caches will be used for both.
 - Full implementation of AMBA-2.0 AHB on-chip bus

The standard release of LEON incorporates a number of peripherals and support blocks which will not be included on SoPEC. The LEON core as used on SoPEC will consist of: 1) the LEON integer unit, 2) the instruction and data caches (currently 1kB each), 3) the cache control logic, 4) the AHB interface and 5) possibly the AHB controller (although this functionality may be implemented in the LEON AHB bridge).

The version of the LEON database that the SoPEC LEON components will be sourced from is LEON2-1.0.7 although later versions may be used if they offer worthwhile functionality or bug fixes that affect the SoPEC design.

The LEON core will be clocked using the system clock, *pclk*, and reset using the *prst_n_section[1]* signal. The ICU will assert all the hardware interrupts using the protocol described in section 11.9. The LEON hardware multipliers and floating-point unit are not required. SoPEC will use the recommended 8 register window configuration.

Further details of the SPARC V8 instruction set and the LEON processor can be found in [36] and [37] respectively.

11.5.1 LEON Registers

Only two of the registers described in the LEON manual are implemented on SoPEC - the LEON configuration register and the Cache Control Register (CCR). The addresses of these registers are shown in Table 16. The configuration register bit fields are described below and the CCR is described in section 11.7.1.1.

11.5.1.1 LEON configuration register

The LEON configuration register allows runtime software to determine the settings of LEONs various configuration options. This is a read-only register whose value for the SoPEC ASIC will be

0x1071_8C00. Further descriptions of many of the bitfields can be found in the LEON manual. The values used for SoPEC are highlighted in bold for clarity.

Table 16. LEON Configuration Register

Field Name	bit(s)	Description			
WriteProtection 1:0		Write protection type.			
		00 - none			
		01 - standard			
PCICore	3:2	PCI core type			
		00 - none			
		01 - InSilicon			
		10 - ESA			
		11 - Other			
FPUType	5:4	FPU type.			
		00 - none			
		01 - Meiko			
MemStatus	6	0 - No memory status and failing address register present			
		1 - Memory status and failing address register present			
Watchdog	7	0 - Watchdog timer not present (Note this refers to the LEON			
		watchdog timer in the LEON timer block).			
		1 - Watchdog timer present			
UMUL/SMUL	8	0 - UMUL/SMUL instructions are not implemented			
		1 - UMUL/SMUL instructions are implemented			
UDIV/SDIV	9	0 - UMUL/SMUL instructions are not implemented			
		1 - UMUL/SMUL instructions are implemented			
DLSZ	11:10	Data cache line size in 32-bit words:			
		00 - 1 word			
		01 - 2 words			
		10 - 4 words			
		11 - 8 words			
DCSZ	14:12	Data cache size in kBbytes = 2 ^{DCSZ} . SoPEC DCSZ = 0.			
ILSZ	16:15	Instruction cache line size in 32-bit words:			
		00 - 1 word			
		01 - 2 words			
		10 - 4 words			
		11 - 8 words			
ICSZ	19:17	Instruction cache size in kBbytes = 2 ^{ICSZ} . SoPEC ICSZ = 0.			
RegWin	24:20	The implemented number of SPARC register windows - 1.			
		SoPEC value = 7.			

UMAC/SMAC	25	0 - UMAC/SMAC instructions are not implemented
		1 - UMAC/SMAC instructions are implemented
Watchpoints	28:26	The implemented number of hardware watchpoints. SoPEC value
		= 4.
SDRAM	29	0 - SDRAM controller not present
		1 - SDRAM controller present
DSU	30	0 - Debug Support Unit not present
		1 - Debug Support Unit present
Reserved	31	Reserved. SoPEC value = 0.

11.6 MEMORY MANAGEMENT UNIT (MMU)

5

25

Memory Management Units are typically used to protect certain regions of memory from invalid accesses, to perform address translation for a virtual memory system and to maintain memory page status (swapped-in, swapped-out or unmapped)

The SoPEC MMU is a much simpler affair whose function is to ensure that all regions of the SoPEC memory map are adequately protected. The MMU does not support virtual memory and physical addresses are used at all times. The SoPEC MMU supports a full 32-bit address space. The SoPEC memory map is depicted in Figure 18 below.

- The MMU selects the relevant bus protocol and generates the appropriate control signals depending on the area of memory being accessed. The MMU is responsible for performing the address decode and generation of the appropriate block select signal as well as the selection of the correct block read bus during a read access. The MMU will need to support all of the bus transactions the CPU can produce including interrupt acknowledge cycles, aborted transactions etc.

 When an MMU error occurs (such as an attempt to access a supervisor mode only region when in user mode) a bus error is generated. While the LEON can recognise different types of bus error
 - (e.g. data store error, instruction access error) it handles them in the same manner as it handles all traps i.e it will transfer control to a trap handler. No extra state information is be stored because of the nature of the trap. The location of the trap handler is contained in the TBR (Trap Base Register).
- This is the same mechanism as is used to handle interrupts.

11.6.1 CPU-bus peripherals address map

The address mapping for the peripherals attached to the CPU-bus is shown in Table 17 below. The MMU performs the decode of the high order bits to generate the relevant *cpu_block_select* signal. Apart from the PCU, which decodes the address space for the PEP blocks, each block only needs to decode as many bits of *cpu_adr[11:2]* as required to address all the registers within the block.

Table 17. CPU-bus peripherals address map

Block_base	Address
ROM_base	0x0000_0000
MMU_base	0x0001_0000

TIM_base	0x0001_1000
LSS_base	0x0001_2000
GPIO_base	0x0001_3000
SCB_base	0x0001_4000
ICU_base	0x0001_5000
CPR_base	0x0001_6000
DIU_base	0x0001_7000
PSS_base	0x0001_8000
Reserved	0x0001_9000 to 0x0001_FFFF
PCU_base	0x0002_0000

11.6.2 DRAM Region Mapping

5

10

The embedded DRAM is broken into 8 regions, with each region defined by a lower and upper bound address and with its own access permissions.

The association of an area in the DRAM address space with a MMU region is completely under software control. Table 18 below gives one possible region mapping. Regions should be defined according to their access requirements and position in memory. Regions that share the same access requirements and that are contiguous in memory may be combined into a single region. The example below is purely for indicative purposes - real mappings are likely to differ significantly from this. Note that the RegionBottom and RegionTop fields in this example include the DRAM base address offset (0x4000_000) which is not required when programming the *RegionNTop* and *RegionNBottom* registers. For more details, see 11.6.5.1 and 11.6.5.2.

Table 18. Example region mapping

Region	RegionBottom	RegionTop	Description
0	0x4000_0000	0x4000_0FFF	Silverbrook OS (supervisor) data
1	0x4000_1000	0x4000_BFFF	Silverbrook OS (supervisor) code
2	0x4000_C000	0x4000_C3FF	Silverbrook (supervisor/user) data
3	0x4000_C400	0x4000_CFFF	Silverbrook (supervisor/user) code
4	0x4026_D000	0x4026_D3FF	OEM (user) data
5	0x4026_D400	0x4026_DFFF	OEM (user) code
6	0x4027_E000	0x4027_FFFF	Shared Silverbrook/OEM space
7	0x4000_D000	0x4026_CFFF	Compressed page store (supervisor data)

11.6.3 Non-DRAM regions

As shown in Figure 18 the DRAM occupies only 2.5 MBytes of the total 4 GB SoPEC address space. The non-DRAM regions of SoPEC are handled by the MMU as follows:

ROM (0x0000_0000 to 0x0000_FFFF): The ROM block will control the access types allowed. The cpu_acode[1:0] signals will indicate the CPU mode and access type and the ROM block will assert rom_cpu_berr if an attempted access is forbidden. The protocol is described in more detail in

section 11.4.3. The ROM block access permissions are hard wired to allow all read accesses except to the *FuseChipID* registers which may only be read in supervisor mode.

MMU Internal Registers (0x0001_0000 to 0x0001_0FFF): The MMU is responsible for controlling the accesses to its own internal registers and will only allow data reads and writes (no instruction fetches) from supervisor data space. All other accesses will result in the *mmu_cpu_berr* signal being asserted in accordance with the CPU native bus protocol.

CPU Subsystem Peripheral Registers (0x0001_1000 to 0x0001_FFFF): Each peripheral block will control the access types allowed. Every peripheral will allow supervisor data accesses (both read and write) and some blocks (e.g. Timers and GPIO) will also allow user data space accesses as outlined in the relevant chapters of this specification. Neither supervisor nor user instruction fetch accesses are allowed to any block as it is not possible to execute code from peripheral registers. The bus protocol is described in section 11.4.3.

PCU Mapped Registers (0x0002_0000 to 0x0002_BFFF): All of the PEP blocks registers which are accessed by the CPU via the PCU will inherit the access permissions of the PCU. These access permissions are hard wired to allow supervisor data accesses only and the protocol used is the same as for the CPU peripherals.

Unused address space (0x0002_C000 to 0x3FFF_FFFF and 0x4028_0000 to 0xFFFF_FFFF): All accesses to the unused portion of the address space will result in the *mmu_cpu_berr* signal being asserted in accordance with the CPU native bus protocol. These accesses will not propagate outside of the MMU i.e. no external access will be initiated.

11.6.4 Reset exception vector and reference zero traps

When a reset occurs the LEON processor starts executing code from address 0x0000_0000. A common software bug is zero-referencing or null pointer de-referencing (where the program attempts to access the contents of address 0x0000_0000). To assist software debug the MMU will assert a bus error every time the locations 0x0000_0000 to 0x0000_000F (i.e. the first 4 words of the reset trap) are accessed after the reset trap handler has legitimately been retrieved immediately after reset.

11.6.5 MMU Configuration Registers

5

10

15

20

25

30

The MMU configuration registers include the RDU configuration registers and two LEON registers. Note that all the MMU configuration registers may only be accessed when the CPU is running in supervisor mode.

Table 19. MMU Configuration Registers

Address offset from MMU_base		#bits	Reset	Description
0x00	Region0Bottom[21:5	17		This register contains the physical address that marks the bottom of region 0
0x04	Region0Top[21:5]	17		This register contains the physical address that marks the top of region 0. Region 0 covers the

				entire address space after reset whereas all

11.6.5.1 RegionTop and RegionBottom registers

5

10

The 20 Mbit of embedded DRAM on SoPEC is arranged as 81920 words of 256 bits each. All region boundaries need to align with a 256-bit word. Thus only 17 bits are required for the *RegionNTop* and *RegionNBottom* registers. Note that the bottom 5 bits of the *RegionNTop* and *RegionNBottom* registers cannot be written to and read as '0' i.e. the *RegionNTop* and *RegionNBottom* registers represent byte-aligned DRAM addresses

Both the *RegionNTop* and *RegionNBottom* registers are inclusive i.e. the addresses in the registers are included in the region. Thus the size of a region is (*RegionNTop - RegionNBottom*) +1 DRAM words.

If DRAM regions overlap (there is no reason for this to be the case but there is nothing to prohibit it either) then only accesses allowed by all overlapping regions are permitted. That is if a DRAM address appears in both Region1 and Region3 (for example) the *cpu_acode* of an access is

checked against the access permissions of both regions. If both regions permit the access then it will proceed but if either or both regions do not permit the access then it will not be allowed. The MMU does not support negatively sized regions i.e. the value of the *RegionNTop* register should always be greater than or equal to the value of the *RegionNBottom* register. If *RegionNTop* is lower in the address map than *RegionNTop* then the region is considered to be zero-sized and is ignored.

When both the *RegionNTop* and *RegionNBottom* registers for a region contain the same value the region is then simply one 256-bit word in length and this corresponds to the smallest possible active region.

10 11.6.5.2 Region Control registers

5

15

Each memory region has a control register associated with it. The *RegionNControl* register is used to set the access conditions for the memory region bounded by the *RegionNTop* and *RegionNBottom* registers. Table 20 describes the function of each bit field in the *RegionNControl* registers. All bits in a *RegionNControl* register are both readable and writable by design. However, like all registers in the MMU, the *RegionNControl* registers can only be accessed by code running in supervisor mode.

Table 20. Region Control Register

Field Name	bit(s)	Description
SupervisorAccess	2:0	Denotes the type of access allowed when the CPU is
		running in Supervisor mode. For each access type a 1
		indicates the access is permitted and a 0 indicates the
		access is not permitted.
		bit0 - Data read access permission
		bit1 - Data write access permission
		bit2 - Instruction fetch access permission
UserAccess 5:3		Denotes the type of access allowed when the CPU is
		running in User mode. For each access type a 1 indicates
		the access is permitted and a 0 indicates the access is not
		permitted.
		bit3 - Data read access permission
		bit4 - Data write access permission
		bit5 - Instruction fetch access permission

11.6.5.3 ExceptionSource Register

The SPARC V8 architecture allows for a number of types of memory access error to be trapped.

These trap types and trap handling in general are described in chapter 7 of the SPARC architecture manual [36]. However on the LEON processor only data_store_error and data_access_exception trap types will result from an external (to LEON) bus error. According to the SPARC architecture manual the processor will automatically move to the next register window (i.e. it decrements the current window pointer) and copies the program counters (PC and nPC) to two local registers in the

new window. The supervisor bit in the PSR is also set and the PSR can be saved to another local register by the trap handler (this does not happen automatically in hardware). The *ExceptionSource* register aids the trap handler by identifying the source of an exception. Each bit in the *ExceptionSource* register is set when the relevant trap condition and should be cleared by the trap handler by writing a '1' to that bit position.

Table 21. ExceptionSource Register

5

10

15

20

Field Name	bit(s)	Description
DramAccessExcptn	0	The permissions of an access did not match those of the DRAM region it was attempting to access. This bit will also be set if an attempt is made to access an undefined DRAM region (i.e. a location that is not within the bounds of any RegionTop/RegionBottom pair)
PeriAccessExcptn		An access violation occurred when accessing a CPU subsystem block. This occurs when the access permissions disagree with those set by the block.
UnusedAreaExcptn	2	An attempt was made to access an unused part of the memory map
LockedWriteExcptn	3	An attempt was made to write to a regions registers (RegionTop/ Bottom/Control) after they had been locked.
ResetHandlerExcptn	4	An attempt was made to access a ROM location between 0x0000_0000 and 0x0000_000F after the reset handler was executed. The most likely cause of such an access is the use of an uninitialised pointer or structure.
TimeoutExcptn	5	A bus timeout condition occurred.

11.6.6 MMU Sub-block partition

As can be seen from Figure 19 and Figure 20 the MMU consists of three principal sub-blocks. For clarity the connections between these sub-blocks and other SoPEC blocks and between each of the sub-blocks are shown in two separate diagrams.

11.6.6.1 LEON AHB Bridge

The LEON AHB bridge consists of an AHB bridge to DIU and an AHB to CPU subsystem bus bridge. The AHB bridge will convert between the AHB and the DIU and CPU subsystem bus protocols but the address decoding and enabling of an access happens elsewhere in the MMU. The AHB bridge will always be a slave on the AHB. Note that the AMBA signals from the LEON core are contained within the ahbso and ahbsi records. The LEON records are described in more detail in section 11.7. Glue logic may be required to assist with enabling memory accesses, endianness coherency, interrupts and other miscellaneous signalling.

Table 22. LEON AHB bridge I/Os

Port name	Pins	1/0	Description
Global SoPEC signals	•	-	
prst_n	1	ln	Global reset. Synchronous to pclk, active low.
pclk	1	ln	Global clock
LEON core to LEON AHB signa	ls (ahbsi	and ahbs	so records)
ahbsi.haddr[31:0]	32	ln	AHB address bus
ahbsi.hwdata[31:0]	32	In	AHB write data bus
ahbso.hrdata[31:0]	32	Out	AHB read data bus
ahbsi.hsel	1	ln	AHB slave select signal
ahbsi.hwrite	1	ln	AHB write signal:
]		1 - Write access
			0 - Read access
ahbsi.htrans	2	İn	Indicates the type of the current transfer:
			00 - IDLE
			01 - BUSY
			10 - NONSEQ
			11 - SEQ
ahbsi.hsize	3	ln	Indicates the size of the current transfer:
			000 - Byte transfer
			001 - Halfword transfer
			010 - Word transfer
			011 - 64-bit transfer (unsupported?)
			1xx - Unsupported larger wordsizes
ahbsi.hburst	3	ln	Indicates if the current transfer forms part of a
			burst and the type of burst:
			000 - SINGLE
			001 - INCR
			010 - WRAP4
	1		011 - INCR4
			100 - WRAP8
			101 - INCR8
			110 - WRAP16
			111 - INCR16
ahbsi.hprot	4	ln	Protection control signals pertaining to the
			current access:
			hprot[0] - Opcode(0) / Data(1) access ´
			hprot[1] - User(0) / Supervisor access
			hprot[2] - Non-bufferable(0) / Bufferable(1)
			access (unsupported)

			hprot[3] - Non-cacheable(0) / Cacheable
			access
ahbsi.hmaster	4	In	Indicates the identity of the current bus master.
			This will always be the LEON core.
ahbsi.hmastlock	1	ln	Indicates that the current master is performing
			a locked sequence of transfers.
ahbso.hready	1	Out	Active high ready signal indicating the access
			has completed
ahbso.hresp	2	Out	Indicates the status of the transfer:
			00 - OKAY
			01 - ERROR
			10 - RETRY
			11 - SPLIT
ahbso.hsplit[15:0]	16	Out	This 16-bit split bus is used by a slave to
			indicate to the arbiter which bus masters should
			be allowed attempt a split transaction. This
			feature will be unsupported on the AHB bridge
Toplevel/ Common LEON AH	B bridge	signals	
cpu_dataout[31:0]	32	Out	Data out bus to both DRAM and peripheral
			devices.
cpu_rwn	1	Out	Read/NotWrite signal. 1 = Current access is a
			read access, 0 = Current access is a write
	ļ		access
icu_cpu_ilevel[3:0]	4	In	An interrupt is asserted by driving the
			appropriate priority level on icu_cpu_ilevel.
			These signals must remain asserted until the
. '			CPU executes an interrupt acknowledge cycle.
cpu_icu_ilevel[3:0]	4	ln	Indicates the level of the interrupt the CPU is
			acknowledging when <i>cpu_iack</i> is high
cpu_iack	1	Out	Interrupt acknowledge signal. The exact timing
			depends on the CPU core implementation
cpu_start_access	1	Out	Start Access signal indicating the start of a data
			transfer and that the cpu_adr, cpu_dataout,
			cpu_rwn and cpu_acode signals are all valid.
			This signal is only asserted during the first
			cycle of an access.
cpu_ben[1:0]	2	Out	Byte enable signals.
dram_cpu_data[255:0]	256	In	Read data from the DRAM.
diu_cpu_rreq	1	Out	Read request to the DIU.
			· · · · · · · · · · · · · · · · · · ·

1	In	Acknowledge from DIU that read request has
		been accepted.
1	In	Signal from DIU indicating that valid read data
		is on the <i>dram_cpu_data</i> bus
1	Out	Signal from the CPU to the DIU indicating that
	:	the data currently on the cpu_diu_wdata bus is
		valid and should be committed to the DIU
		posted write buffer
1	In	Signal from the DIU indicating that the posted
	:	write buffer is empty
18	Out	Write address bus to the DIU
128	Out	Write data bus to the DIU
16	Out	Write mask for the <i>cpu_diu_wdata</i> bus. Each
		bit corresponds to a byte of the 128-bit
		cpu_diu_wdata bus.
ntrol Bloc	k signals	
32	Out	CPU Address Bus.
32	In	Data bus from the MMU
1	In	Ready signal from the MMU
2	Out	Access code signals to the MMU

Description:

5

10

·15

The LEON AHB bridge must ensure that all CPU bus transactions are functionally correct and that the timing requirements are met. The AHB bridge also implements a 128-bit DRAM write buffer to improve the efficiency of DRAM writes, particularly for multiple successive writes to DRAM. The AHB bridge is also responsible for ensuring endianness coherency i.e. guaranteeing that the correct data appears in the correct position on the data buses (*hrdata, cpu_dataout* and *cpu_mmu_wdata*) for every type of access. This is a requirement because the LEON uses big-endian addressing while the rest of SoPEC is little-endian.

The LEON AHB bridge will assert request signals to the DIU if the MMU control block deems the access to be a legal access. The validity (i.e. is the CPU running in the correct mode for the address space being accessed) of an access is determined by the contents of the relevant *RegionNControl* register. As the SPARC standard requires that all accesses are aligned to their word size (i.e. byte, half-word, word or double-word) and so it is not possible for an access to traverse a 256-bit boundary (as required by the DIU). Invalid DRAM accesses are not propagated to the DIU and will result in an error response (ahbso.hresp = '01') on the AHB. The DIU bus protocol

is described in more detail in section 20.9. The DIU will return a 256-bit dataword on dram cpu data[255:0] for every read access.

The CPU subsystem bus protocol is described in section 11.4.3. While the LEON AHB bridge performs the protocol translation between AHB and the CPU subsystem bus the select signals for each block are generated by address decoding in the CPU subsystem bus interface. The CPU subsystem bus interface also selects the correct read data bus, ready and error signals for the block being addressed and passes these to the LEON AHB bridge which puts them on the AHB bus. It is expected that some signals (especially those external to the CPU block) will need to be registered here to meet the timing requirements. Careful thought will be required to ensure that overall CPU access times are not excessively degraded by the use of too many register stages.

11.6.6.1.1 DRAM write buffer

5

10

15

20

25

30

35

The DRAM write buffer improves the efficiency of DRAM writes by aggregating a number of CPU write accesses into a single DIU write access. This is achieved by checking to see if a CPU write is to an address already in the write buffer and if so the write is immediately acknowledged (i.e. the ahbsi.hready signal is asserted without any wait states) and the DRAM write buffer updated accordingly. When the CPU write is to a DRAM address other than that in the write buffer then the current contents of the write buffer are sent to the DIU (where they are placed in the posted write buffer) and the DRAM write buffer is updated with the address and data of the CPU write. The DRAM write buffer consists of a 128-bit data buffer, an 18-bit write address tag and a 16-bit write mask. Each bit of the write mask indicates the validity of the corresponding byte of the write buffer as shown in Figure 21 below.

The operation of the DRAM write buffer is summarised by the following set of rules:

- 1) The DRAM write buffer only contains DRAM write data i.e. peripheral writes go directly to the addressed peripheral.
- 2) CPU writes to locations within the DRAM write buffer or to an empty write buffer (i.e. the write mask bits are all 0) complete with zero wait states regardless of the size of the write (byte/half-word/word/ double-word).
- 3) The contents of the DRAM write buffer are flushed to DRAM whenever a CPU write to a location outside the write buffer occurs, whenever a CPU read from a location within the write buffer occurs or whenever a write to a peripheral register occurs.
- 4) A flush resulting from a peripheral write will not cause any extra wait states to be inserted in the peripheral write access.
- 5) Flushes resulting from a DRAM accesses will cause wait states to be inserted until the DIU posted write buffer is empty. If the DIU posted write buffer is empty at the time the flush is required then no wait states will be inserted for a flush resulting from a CPU write or one wait state will be inserted for a flush resulting from a CPU read (this is to ensure that the DIU sees the write request ahead of the read request). Note that in this case further wait states will also be inserted as a result of the delay in servicing the read request by the DIU.
- 40 11.6.6.1.2 DIU interface waveforms

Figure 22 below depicts the operation of the AHB bridge over a sample sequence of DRAM transactions consisting of a read into the DCache, a double-word store to an address other than that currently in the DRAM write buffer followed by an ICache line refill. To avoid clutter a number of AHB control signals that are inputs to the MMU have been grouped together as ahbsi.CONTROL and only the ahbso.HREADY is shown of the output AHB control signals.

The first transaction is a single word load ('LD'). The MMU (specifically the MMU control block) uses the first cycle of every access (i.e. the address phase of an AHB transaction) to determine whether or not the access is a legal access. The read request to the DIU is then asserted in the following cycle (assuming the access is a valid one) and is acknowledged by the DIU a cycle later. Note that the time from <code>cpu_diu_rreq</code> being asserted and <code>diu_cpu_rack</code> being asserted is variable as it depends on the DIU configuration and access patterns of DIU requestors. The AHB bridge will insert wait states until it sees the <code>diu_cpu_rvalid</code> signal is high, indicating the data ('LD1') on the <code>dram_cpu_data</code> bus is valid. The AHB bridge terminates the read access in the same cycle by asserting the ahbso.HREADY signal (together with an 'OKAY' HRESP code). The AHB bridge also selects the appropriate 32 bits ('RD1') from the 256-bit DRAM line data ('LD1') returned by the DIU corresponding to the word address given by A1.

The second transaction is an AHB two-beat incrementing burst issued by the LEON acache block in response to the execution of a double-word store instruction. As LEON is a big endian processor the address issued ('A2') during the address phase of the first beat of this transaction is the address of the most significant word of the double-word while the address for the second beat ('A3') is that of the least significant word i.e. A3 = A2 +4. The presence of the DRAM write buffer allows these writes to complete without the insertion of any wait states. This is true even when, as shown here, the DRAM write buffer needs to be flushed into the DIU posted write buffer, provided the DIU posted write buffer is empty. If the DIU posted write buffer is not empty (as would be signified by diu_cpu_write_rdy being low) then wait states would be inserted until it became empty. The cpu_diu_wdata buffer builds up the data to be written to the DIU over a number of transactions ('BD1' and 'BD2' here) while the cpu_diu_wmask records every byte that has been written to since the last flush - in this case the lowest word and then the second lowest word are written to as a result of the double-word store operation.

The final transaction shown here is a DRAM read caused by an ICache miss. Note that the pipelined nature of the AHB bus allows the address phase of this transaction to overlap with the final data phase of the previous transaction. All ICache misses appear as single word loads ('LD') on the AHB bus. In this case we can see that the DIU is slower to respond to this read request than to the first read request because it is processing the write access caused by the DRAM write buffer flush. The ICache refill will complete just after the window shown in Figure 22.

11.6.6.2 CPU Subsystem Bus Interface

The CPU Subsystem Interface block handles all valid accesses to the peripheral blocks that comprise the CPU Subsystem.

Table 23. CPU Subsystem Bus Interface I/Os

Same and a Marian					

Description:

The CPU Subsystem Bus Interface block performs simple address decoding to select a peripheral and multiplexing of the returned signals from the various peripheral blocks. The base addresses used for the decode operation are defined in Table . Note that access to the MMU configuration registers are handled by the MMU Control Block rather than the CPU Subsystem Bus Interface block. The CPU Subsystem Bus Interface block operation is described by the following pseudocode:

```
masked_cpu_adr = cpu_adr[17:12]
case (masked_cpu_adr)
```

```
when TIM base[17:12]
                        cpu_tim_sel = peri_access_en // The peri_access_en
                 signal will have the
                       peri_mmu_data = tim_cpu_data

25 11.6.6.3 MMU Control Block

The MMU Control Block determines whether every CPU access is a valid access. No more than one cycle is to be consumed in determining the validity of an access and all accesses must terminate with the assertion of either <code>mmu_cpu_rdy</code> or <code>mmu_cpu_berr</code>. To safeguard against stalling the CPU a simple bus timeout mechanism will be supported.

30 Table 24. MMU Control Block I/Os

Port name	Pins	1/0	Description
Global SoPEC signal	s	.L.	
prst_n	1	ln	Global reset. Synchronous to pclk, active low.
pclk	1	ln	Global clock
Toplevel/Common M	MU Contr	ol Bloci	k signals
cpu_adr[21:2]	22	Out	Address bus for both DRAM and peripheral access.
cpu_acode[1:0]	2	Out	CPU access code signals (cpu_mmu_acode) retimed to meet the CPU Subsystem Bus timing requirements
dram_access_en	1	Out	DRAM Access Enable signal. Indicates that the current CPU access is a valid DRAM access.
MMU Control Block to	LEON A	HB brid	dge signals

cpu_mmu_adr[31:0]	32	ln	CPU core address bus.
cpu_dataout[31:0]	32	ln	Toplevel CPU data bus
mmu_cpu_data[31:0]	32	Out	Data bus to the CPU core. Carries the data for all
			CPU read operations
cpu_rwn	1	In	Toplevel CPU Read/notWrite signal.
cpu_mmu_acode[1:0]	2	In	CPU access code signals
mmu_cpu_rdy	1	Out	Ready signal to the CPU core. Indicates the
			completion of all valid CPU accesses.
mmu_cpu_berr	1	Out	Bus Error signal to the CPU core. This signal is
			asserted to terminate an invalid access.
cpu_start_access	1	ln	Start Access signal from the LEON AHB bridge
			indicating the start of a data transfer and that the
			cpu_adr, cpu_dataout, cpu_rwn and cpu_acode
			signals are all valid. This signal is only asserted
			during the first cycle of an access.
cpu_iack	1	In	Interrupt Acknowledge signal from the CPU. This
			signal is only asserted during an interrupt
			acknowledge cycle.
cpu_ben[1:0]	2	In	Byte enable signals indicating which bytes of the 32-
			bit bus are being accessed.
MMU Control Block to C	PU S	ubsyster	n Bus Interface signals
cpu_adr[17:12]	8	Out	Toplevel CPU Address bus. Only bits 17-12 are
			required to decode the peripherals address space
peri_access_en	1	Out	Enable Access signal. A peripheral access cannot be
			initiated unless it has been enabled by the MMU
			Control Unit
peri_mmu_data[31:0]	32	ln	Data bus from the selected peripheral
peri_mmu_rdy	1	ln	Data Ready signal. Indicates the data on the
			peri_mmu_data bus is valid for a read cycle or that
			the data was successfully written to the peripheral for
			a write cycle.
peri_mmu_berr	1	in	Bus Error signal. Indicates a bus error has occurred in
			accessing the selected peripheral
Description:			

Description:

5

The MMU Control Block is responsible for the MMU's core functionality, namely determining whether or not an access to any part of the address map is valid. An access is considered valid if it is to a mapped area of the address space and if the CPU is running in the appropriate mode for that address space. Furthermore the MMU control block must correctly handle the special cases that are: an interrupt acknowledge cycle, a reset exception vector fetch, an access that crosses a 256-

bit DRAM word boundary and a bus timeout condition. The following pseudocode shows the logic required to implement the MMU Control Block functionality. It does not deal with the timing relationships of the various signals - it is the designer's responsibility to ensure that these relationships are correct and comply with the different bus protocols. For simplicity the pseudocode is split up into numbered sections so that the functionality may be seen more easily. It is important to note that the style used for the pseudocode will differ from the actual coding style used in the RTL implementation. The pseudocode is only intended to capture the required functionality, to clearly show the criteria that need to be tested rather than to describe how the implementation should be performed. In particular the different comparisons of the address used to determine which part of the memory map, which DRAM region (if applicable) and the permission checking should all be performed in parallel (with results ORed together where appropriate) rather than sequentially as the pseudocode implies.

PS0 Description: This first segment of code defines a number of constants and variables that are used elsewhere in this description. Most signals have been defined in the I/O descriptions of the MMU sub-blocks that precede this section of the document. The *post_reset_state* variable is used later (in section PS4) to determine if we should trap a null pointer access.

                    function. This is done in PS6
                      end
10
      PS2 Description: Accesses to the large unused area of the address space are trapped by this
      section. No bus transactions are initiated and the mmu_cpu_berr signal is asserted.
                      elsif (cpu mmu adr >= UnusedBottom) then
                         peri access en = 0
                                                 // The access is to an invalid area
15
                   of the address space
                         dram_access_en = 0
                         mmu cpu berr = 1
                         mmu cpu rdy = 0
20
      PS3 Description: This section deals with accesses to CPU Subsystem peripherals, including the
      MMU itself. If the MMU registers are being accessed then no external bus transactions are required.
      Access to the MMU registers is only permitted if the CPU is making a data access from supervisor
      mode, otherwise a bus error is asserted and the access terminated. For non-MMU accesses then
      transactions occur over the CPU Subsystem Bus and each peripheral is responsible for determining
25
      whether or not the CPU is in the correct mode (based on the cpu_acode signals) to be permitted
      access to its registers. Note that all of the PEP registers are accessed via the PCU which is on the
      CPU Subsystem Bus.
                   PS3:
30

                           mmu_cpu_rdy = 0
20
```

PS6 Description: This final section of pseudocode deals with the special case of a bus timeout. This occurs when an access has been initiated but has not completed before the *BusTimeout* number of *pclk* cycles. While access to both DRAM and CPU/PEP Subsystem registers will take a variable number of cycles (due to DRAM traffic, PCU command execution or the different timing required to access registers in imported IP) each access should complete before a timeout occurs. Therefore it should not be possible to stall the CPU by locking either the CPU Subsystem or DIU buses. However given the fatal effect such a stall would have it is considered prudent to implement bus timeout detection.

```
30
                 PS6:
                   // Only thing remaining is to implement a bus timeout
                 function.
                   if ((cpu_start_access == 1) then
35
                     access initiated = TRUE

                 (BusTimeout != 0))
45
                      if (timeout countdown > 0) then
```

11.7 LEON CACHES

The version of LEON implemented on SoPEC features 1 kB of ICache and 1 kB of DCache. Both caches are direct mapped and feature 8 word lines so their data RAMs are arranged as 32 x 256-bit and their tag RAMs as 32 x 30-bit (itag) or 32 x 32-bit (dtag). Like most of the rest of the LEON code used on SoPEC the cache controllers are taken from the leon2-1.0.7 release. The LEON cache controllers and cache RAMs have been modified to ensure that an entire 256-bit line is refilled at a time to make maximum use out of the memory bandwidth offered by the embedded DRAM organization (DRAM lines are also 256-bit). The data cache controller has also been modified to ensure that user mode code cannot access the DCache contents unless it is authorised to do so. A block diagram of the LEON CPU core as implemented on SoPEC is shown in Figure 23 below. In this diagram dotted lines are used to indicate hierarchy and red items represent signals or wrappers added as part of the SoPEC modifications. LEON makes heavy use of VHDL records and the records used in the CPU core are described in Table 25. Unless otherwise stated the records are defined in the iface.vhd file (part of the LEON release) and this should be consulted for a complete breakdown of the record elements.

Table 25. Relevant LEON records

Record Name	Description
rfi	Register File Input record. Contains address, datain and control signals for the register file.
rfo	Register File Output record. Contains the data out of the dual read port register file.
ici	Instruction Cache In record. Contains program counters from different stages of the pipeline and various control signals
ico	Instruction Cache Out record. Contains the fetched instruction data and various control signals. This record is also sent to the DCache (i.e. icol) so that diagnostic accesses (e.g. <i>Ida/sta</i>) can be serviced.
dci	Data Cache In record. Contains address and data buses from different stages of the pipeline (execute & memory) and various control signals
dco	Data Cache Out record. Contains the data retrieved from either memory or the caches and various control signals. This record is also sent to the ICache (i.e. dcol) so that diagnostic accesses (e.g. <i>Ida/sta</i>) can be serviced.
iui .	Integer Unit In record. This record contains the interrupt request level and a record for use with LEONs Debug Support Unit (DSU)

iuo	Integer Unit Out record. This record contains the acknowledged interrupt
	request level with control signals and a record for use with LEONs Debug
	Support Unit (DSU)
mcii	Memory to Cache Icache In record. Contains the address of an Icache miss
	and various control signals
mcio	Memory to Cache Icache Out record. Contains the returned data from memory
	and various control signals
mcdi	Memory to Cache Dcache In record. Contains the address and data of a
	Dcache miss or write and various control signals
mcdo	Memory to Cache Dcache Out record. Contains the returned data from
	memory and various control signals
ahbi	AHB In record. This is the input record for an AHB master and contains the
	data bus and AHB control signals. The destination for the signals in this record
	is the AHB controller. This record is defined in the amba.vhd file
ahbo	AHB Out record. This is the output record for an AHB master and contains the
	address and data buses and AHB control signals. The AHB controller drives
	the signals in this record. This record is defined in the amba.vhd file
ahbsi	AHB Slave In record. This is the input record for an AHB slave and contains
	the address and data buses and AHB control signals. It is used by the DCache
	to facilitate cache snooping (this feature is not enabled in SoPEC). This record
	is defined in the amba.vhd file
crami	Cache RAM In record. This record is composed of records of records which
	contain the address, data and tag entries with associated control signals for
	both the ICache RAM and DCache RAM
cramo	Cache RAM Out record. This record is composed of records of records which
	contain the data and tag entries with associated control signals for both the
	ICache RAM and DCache RAM
iline_rdy	Control signal from the ICache controller to the instruction cache memory. This
	signal is active (high) when a full 256-bit line (on dram_cpu_data) is to be
	written to cache memory.
dline_rdy	Control signal from the DCache controller to the data cache memory. This
	signal is active (high) when a full 256-bit line (on dram_cpu_data) is to be
	written to cache memory.
dram_cpu_data	256-bit data bus from the embedded DRAM

11.7.1 Cache controllers

The LEON cache module consists of three components: the ICache controller (icache.vhd), the DCache controller (dcache.vhd) and the AHB bridge (acache.vhd) which translates all cache misses into memory requests on the AHB bus.

In order to enable full line refill operation a few changes had to be made to the cache controllers.

The ICache controller was modified to ensure that whenever a location in the cache was updated

(i.e. the cache was enabled and was being refilled from DRAM) all locations on that cache line had their valid bits set to reflect the fact that the full line was updated. The *iline_rdy* signal is asserted by the ICache controller when this happens and this informs the cache wrappers to update all locations in the idata RAM for that line.

A similar change was made to the DCache controller except that the entire line was only updated following a read miss and that existing write through operation was preserved. The DCache controller uses the *dline_rdy* signal to instruct the cache wrapper to update all locations in the ddata RAM for a line. An additional modification was also made to ensure that a double-word load instruction from a non-cached location would only result in one read access to the DIU i.e. the second read would be serviced by the data cache. Note that if the DCache is turned off then a double-word load instruction will cause two DIU read accesses to occur even though they will both be to the same 256-bit DRAM line.

15

20

25

30

35

The DCache controller was further modified to ensure that user mode code cannot access cached data to which it does not have permission (as determined by the relevant RegionNControl register settings at the time the cache line was loaded). This required an extra 2 bits of tag information to record the user read and write permissions for each cache line. These user access permissions can be updated in the same manner as the other tag fields (i.e. address and valid bits) namely by line refill, STA instruction or cache flush. The user access permission bits are checked every time user code attempts to access the data cache and if the permissions of the access do not agree with the permissions returned from the tag RAM then a cache miss occurs. As the MMU evaluates the access permissions for every cache miss it will generate the appropriate exception for the forced cache miss caused by the errant user code. In the case of a prohibited read access the trap will be immediate while a prohibited write access will result in a deferred trap. The deferred trap results from the fact that the prohibited write is committed to a write buffer in the DCache controller and program execution continues until the prohibited write is detected by the MMU which may be several cycles later. Because the errant write was treated as a write miss by the DCache controller (as it did not match the stored user access permissions) the cache contents were not updated and so remain coherent with the DRAM contents (which do not get updated because the MMU intercepted the prohibited write). Supervisor mode code is not subject to such checks and so has free access to the contents of the data cache.

In addition to AHB bridging, the ACache component also performs arbitration between ICache and DCache misses when simultaneous misses occur (the DCache always wins) and implements the Cache Control Register (CCR). The leon2-1.0.7 release is inconsistent in how it handles cacheability: For instruction fetches the cacheability (i.e. is the access to an area of memory that is cacheable) is determined by the ICache controller while the ACache determines whether or not a data access is cacheable. To further complicate matters the DCache controller does determine if an access resulting from a cache snoop by another AHB master is cacheable (Note that the SoPEC ASIC does not implement cache snooping as it has no need to do so). This inconsistency has been cleaned up in more recent LEON releases but is preserved here to minimise the number of changes

to the LEON RTL. The cache controllers were modified to ensure that only DRAM accesses (as defined by the SoPEC memory map) are cached.

The only functionality removed as a result of the modifications was support for burst fills of the ICache. When enabled burst fills would refill an ICache line from the location where a miss occurred up to the end of the line. As the entire line is now refilled at once (when executing from DRAM) this functionality is no longer required. Furthermore more substantial modifications to the ICache controller would be needed if we wished to preserve this function without adversely affecting full line refills. The CCR was therefore modified to ensure that the instruction burst fetch bit (bit16) was tied low and could not be written to.

10 11.7.1.1 LEON Cache Control Register

5

15

The CCR controls the operation of both the I and D caches. Note that the bitfields used on the SoPEC implementation of this register are based on the LEON v1.0.7 implementation and some bits have their values tied off. See section 4 of the LEON manual for a description of the LEON cache controllers.

Table 26. LEON Cache Control Register

Field Name	bit(s)	Description
ics	1:0	Instruction cache state:
į		00 - disabled
		01 - frozen
		10 - disabled
		11 - enabled
Reserved	13:6	Reserved. Reads as 0.
DCS	3:2	Data cache state:
		00 - disabled
		01 - frozen
		10 - disabled
		11 - enabled
IF	4	lCache freeze on interrupt
		0 - Do not freeze the lCache contents on taking an interrupt
		1 - Freeze the ICache contents on taking an interrupt
DF	5	DCache freeze on interrupt
		0 - Do not freeze the DCache contents on taking an interrupt
		1 - Freeze the DCache contents on taking an interrupt
Reserved	13:6	Reserved. Reads as 0.
DP	14	Data cache flush pending.
		0 - No DCache flush in progress
		1 - DCache flush in progress
		This bit is ReadOnly.

IP	15	Instruction cache flush pending.
		0 - No lCache flush in progress
		1 - ICache flush in progress
		This bit is ReadOnly.
IB	16	Instruction burst fetch enable. This bit is tied low on SoPEC because it
		would interfere with the operation of the cache wrappers. Burst refill
		functionality is automatically provided in SoPEC by the cache
		wrappers.
Reserved	20:17	Reserved. Reads as 0.
	20:17	Reserved. Reads as 0. Flush instruction cache. Writing a 1 this bit will flush the ICache. Reads
Reserved FI FD		Flush instruction cache. Writing a 1 this bit will flush the ICache. Reads
FI	21	Flush instruction cache. Writing a 1 this bit will flush the ICache. Reads as 0.
	21	Flush instruction cache. Writing a 1 this bit will flush the ICache. Reads as 0. Flush data cache. Writing a 1 this bit will flush the DCache. Reads as
FI	21	Flush instruction cache. Writing a 1 this bit will flush the ICache. Reads as 0. Flush data cache. Writing a 1 this bit will flush the DCache. Reads as 0.

11.7.2 Cache wrappers

The cache RAMs used in the leon2-1.0.7 release needed to be modified to support full line refills and the correct IBM macros also needed to be instantiated. Although they are described as RAMs throughout this document (for consistency), register arrays are actually used to implement the cache RAMs. This is because IBM SRAMs were not available in suitable configurations (offered configurations were too big) to implement either the tag or data cache RAMs. Both instruction and data tag RAMs are implemented using dual port (1 Read & 1 Write) register arrays and the clocked write-through versions of the register arrays were used as they most closely approximate the single port SRAM LEON expects to see.

10 11.7.2.1 Cache Tag RAM wrappers

The itag and dtag RAMs differ only in their width - the itag is a 32x30 array while the dtag is a 32x32 array with the extra 2 bits being used to record the user access permissions for each line. When read using a LDA instruction both tags return 32-bit words. The tag fields are described in Table 27 and Table 28 below. Using the IBM naming conventions the register arrays used for the tag RAMs are called RA032X30D2P2W1R1M3 for the itag and RA032X32D2P2W1R1M3 for the dtag. The *ibm_syncram* wrapper used for the tag RAMs is a simple affair that just maps the wrapper ports on to the appropriate ports of the IBM register array and ensures the output data has the correct timing by registering it. The tag RAMs do not require any special modifications to handle full line refills.

Table 27. LEON Instruction Cache Tag

Field Name bit(s) Description

Valid 7:0 Each valid bit indicates whether or not the corresponding word of the cache line contains valid data

20

15

Reserved	9:8	Reserved - these bits do not exist in the itag RAM. Reads as
		0.
Address	31:10	The tag address of the cache line

Table 28. LEON Data Cache Tag

Field Name	bit(s)	Description
Valid	7:0	Each valid bit indicates whether or not the corresponding word of the cache line contains valid data
URP	8	User read permission. 0 - User mode reads will force a refill of this line 1 - User mode code can read from this cache line.
UWP	9	User write permission. 0 - User mode writes will not be written to the cache 1 - User mode code can write to this cache line.
Address	31:10	The tag address of the cache line

11.7.2.2 Cache Data RAM wrappers

- The cache data RAM contains the actual cached data and nothing else. Both the instruction and data cache data RAMs are implemented using 8 32x32-bit register arrays and some additional logic to support full line refills. Using the IBM naming conventions the register arrays used for the tag RAMs are called RA032X32D2P2W1R1M3. The *ibm_cdram_wrap* wrapper used for the tag RAMs is shown in Figure 24 below.
- To the cache controllers the cache data RAM wrapper looks like a 256x32 single port SRAM (which is what they expect to see) with an input to indicate when a full line refill is taking place (the *line_rdy* signal). Internally the 8-bit address bus is split into a 5-bit lineaddress, which selects one of the 32 256-bit cache lines, and a 3-bit wordaddress which selects one of the 8 32-bit words on the cache line. Thus each of the 8 32x32 register arrays contains one 32-bit word of each cache line. When a full line is being refilled (indicated by both the *line_rdy* and *write* signals being high) every register array is written to with the appropriate 32 bits from the *linedatain* bus which contains the 256-bit line returned by the DIU after a cache miss. When just one word of the cache line is to be written (indicated by the *write* signal being high while the *line_rdy* is low) then the wordaddress is used to enable the write signal to the selected register array only all other write enable signals are kept low. The data cache controller handles byte and half-word write by means of a read-modify-write operation so writes to the cache data RAM are always 32-bit.

The wordaddress is also used to select the correct 32-bit word from the cache line to return to the LEON integer unit.

11.8 REALTIME DEBUG UNIT (RDU)

The RDU facilitates the observation of the contents of most of the CPU addressable registers in the SoPEC device in addition to some pseudo-registers in realtime. The contents of pseudo-registers, i.e. registers that are collections of otherwise unobservable signals and that do not affect the

functionality of a circuit, are defined in each block as required. Many blocks do not have pseudoregisters and some blocks (e.g. ROM, PSS) do not make debug information available to the RDU as it would be of little value in realtime debug.

Each block that supports realtime debug observation features a *DebugSelect* register that controls a local mux to determine which register is output on the block's data bus (i.e. *block_cpu_data*). One small drawback with reusing the blocks data bus is that the debug data cannot be present on the same bus during a CPU read from the block. An accompanying active high *block_cpu_debug_valid* signal is used to indicate when the data bus contains valid debug data and when the bus is being used by the CPU. There is no arbitration for the bus as the CPU will always have access when required. A block diagram of the RDU is shown in Figure 25.

Table 29. RDU I/Os

5

Port name	Pins	1/0	Description
diu_cpu_data	32	ln	Read data bus from the DIU block
cpr_cpu_data	32	In	Read data bus from the CPR block
gpio_cpu_data	32	in	Read data bus from the GPIO block
icu_cpu_data	32	ln	Read data bus from the ICU block
lss_cpu_data	32	ln	Read data bus from the LSS block
pcu_cpu_debug_data	32	In	Read data bus from the PCU block
scb_cpu_data	32	ln	Read data bus from the SCB block
tim_cpu_data	32	ln	Read data bus from the TIM block
diu_cpu_debug_valid	1	ln	Signal indicating the data on the diu_cpu_data bus is
			valid debug data.
tim_cpu_debug_valid	1	ln	Signal indicating the data on the tim_cpu_data bus is
			valid debug data.
scb_cpu_debug_valid	1.	In	Signal indicating the data on the scb_cpu_data bus is
			valid debug data.
pcu_cpu_debug_valid	1	ln	Signal indicating the data on the pcu_cpu_data bus is
			valid debug data.
lss_cpu_debug_valid	1	In	Signal indicating the data on the Iss_cpu_data bus is
			valid debug data.
icu_cpu_debug_valid	1	ln	Signal indicating the data on the icu_cpu_data bus is
			valid debug data.
gpio_cpu_debug_valid	1	ln	Signal indicating the data on the gpio_cpu_data bus is
			valid debug data.
cpr_cpu_debug_valid	1	ln	Signal indicating the data on the cpr_cpu_data bus is
			valid debug data.
debug_data_out	32	Out	Output debug data to be muxed on to the
			PHI/GPIO/other pins

debug_data_valid	1	Out	Debug valid signal indicating the validity of the data on
			debug_data_out. This signal is used in all debug
			configurations
debug_cntrl	33	Out	Control signal for each debug data line indicating
			whether or not the debug data should be selected by
			the pin mux

As there are no spare pins that can be used to output the debug data to an external capture device some of the existing I/Os will have a debug multiplexer placed in front of them to allow them be used as debug pins. Furthermore not every pin that has a debug mux will always be available to carry the debug data as they may be engaged in their primary purpose e.g. as a GPIO pin. The RDU therefore outputs a debug_cntrl signal with each debug data bit to indicate whether the mux associated with each debug pin should select the debug data or the normal data for the pin. The DebugPinSel1 and DebugPinSel2 registers are used to determine which of the 33 potential debug pins are enabled for debug at any particular time.

- As it may not always be possible to output a full 32-bit debug word every cycle the RDU supports the outputting of an n-bit sub-word every cycle to the enabled debug pins. Each debug test would then need to be re-run a number of times with a different portion of the debug word being output on the n-bit sub-word each time. The data from each run should then be correlated to create a full 32-bit (or whatever size is needed) debug word for every cycle. The debug_data_valid and pclk_out signals will accompany every sub-word to allow the data to be sampled correctly. The pclk_out signal is sourced close to its output pad rather than in the RDU to minimise the skew between the rising edge of the debug data signals (which should be registered close to their output pads) and the rising edge of pclk_out.
 - As multiple debug runs will be needed to obtain a complete set of debug data the n-bit sub-word will need to contain a different bit pattern for each run. For maximum flexibility each debug pin has an associated *DebugDataSrc* register that allows any of the 32 bits of the debug data word to be output on that particular debug data pin. The debug data pin must be enabled for debug operation by having its corresponding bit in the *DebugPinSel* registers set for the selected debug data bit to appear on the pin.
- The size of the sub-word is determined by the number of enabled debug pins which is controlled by the <code>DebugPinSel</code> registers. Note that the <code>debug_data_valid</code> signal is always output. Furthermore <code>debug_cntrl[0]</code> (which is configured by <code>DebugPinSel1</code>) controls the mux for both the <code>debug_data_valid</code> and <code>pclk_out</code> signals as both of these must be enabled for any debug operation. The mapping of <code>debug_data_out[n]</code> signals onto individual pins will take place outside the RDU.
- This mapping is described in Table 30 below.

Table 30. DebugPinSel mapping

5

bit#	Pin
DebugPinSel1	phi_frclk. The <i>debug_data_valid</i> signal will appear

	on this pin when enabled. Enabling this pin also		
	automatically enables the phi_readl pin which will		
	output the <i>pclk_out</i> signal		
DebugPinSel2(0-31)	gpio[031]		

Table 31. RDU Configuration Registers

Address offset from	Register	#bits	Reset	Description
MMU_base				
0x80	DebugSrc	4	0x00	Denotes which block is supplying the debug
				data. The encoding of this block is given
				below.
				0 - MMU
				1 - TIM
				2 - LSS
				3- GPIO
				4 - SCB
				5 - ICU
				6 - CPR
				7 - DIU
				8 – PCU
0x84	DebugPinSel	1	0x0	Determines whether the phi_frclk and
	1			phi_readl pins are used for debug output.
				1 - Pin outputs debug data
				0 - Normal pin function
0x88	DebugPinSel	32	0x000	Determines whether a pin is used for debug
	2		0_000	data output.
			0	1 - Pin outputs debug data
			•	0 - Normal pin function
0x8C to 0x108	DebugDataSr	32 x 5	0x00	Selects which bit of the 32-bit debug data
	c[31:0]			word will be output on debug_data_out[N]

11.9 INTERRUPT OPERATION

5

10

The interrupt controller unit (see chapter 14) generates an interrupt request by driving interrupt request lines with the appropriate interrupt level. LEON supports 15 levels of interrupt with level 15 as the highest level (the SPARC architecture manual [36] states that level 15 is non-maskable but we have the freedom to mask this if desired). The CPU will begin processing an interrupt exception when execution of the current instruction has completed and it will only do so if the interrupt level is higher than the current processor priority. If a second interrupt request arrives with the same level as an executing interrupt service routine then the exception will not be processed until the executing routine has completed.

When an interrupt trap occurs the LEON hardware will place the program counters (PC and nPC) into two local registers. The interrupt handler routine is expected, as a minimum, to place the PSR register in another local register to ensure that the LEON can correctly return to its pre-interrupt state. The 4-bit interrupt level (*irl*) is also written to the trap type (*tt*) field of the TBR (Trap Base

Register) by hardware. The TBR then contains the vector of the trap handler routine the processor will then jump. The TBA (Trap Base Address) field of the TBR must have a valid value before any interrupt processing can occur so it should be configured at an early stage.

Interrupt pre-emption is supported while ET (Enable Traps) bit of the PSR is set. This bit is cleared during the initial trap processing. In initial simulations the ET bit was observed to be cleared for up to 30 cycles. This causes significant additional interrupt latency in the worst case where a higher priority interrupt arrives just as a lower priority one is taken.

The interrupt acknowledge cycles shown in Figure 26 below are derived from simulations of the LEON processor. The SoPEC toplevel interrupt signals used in this diagram map directly to the LEON interrupt signals in the *iui* and *iuo* records. An interrupt is asserted by driving its (encoded)

level on the <code>icu_cpu_ilevel[3:0]</code> signals (which map to <code>iui.irl[3:0]</code>). The LEON core responds to this, with variable timing, by reflecting the level of the taken interrupt on the <code>cpu_icu_ilevel[3:0]</code> signals (mapped to <code>iuo.irl[3:0]</code>) and asserting the acknowledge signal <code>cpu_iack</code> (<code>iuo.intack</code>). The interrupt controller then removes the interrupt level one cycle after it has seen the level been acknowledged by the core. If there is another pending interrupt (of lower priority) then this should be driven on <code>icu_cpu_ilevel[3:0]</code> and the CPU will take that interrupt (the level 9 interrupt in the example below)

icu_cpu_ilevel[3:0] and the CPU will take that interrupt (the level 9 interrupt in the example below) once it has finished processing the higher priority interrupt. The cpu_icu_ilevel[3:0] signals always reflect the level of the last taken interrupt, even when the CPU has finished processing all interrupts.

11.10 BOOT OPERATION

See section 17.2 for a description of the SoPEC boot operation.

25 11.11 SOFTWARE DEBUG

10

30

40

Software debug mechanisms are discussed in the "SoPEC Software Debug" document [15]. 12 Serial Communications Block (SCB)

12.1 OVERVIEW

The Serial Communications Block (SCB) handles the movement of all data between the SoPEC and the host device (e.g. PC) and between master and slave SoPEC devices. The main components of the SCB are a Full-Speed (FS) USB Device Core, a FS USB Host Core, a Inter-SoPEC Interface (ISI), a DMA manager, the SCB Map and associated control logic. The need for these components and the various types of communication they provide is evident in a multi-SoPEC printer configuration.

35 12.1.1 Multi-SoPEC systems

While single SoPEC systems are expected to form the majority of SoPEC systems the SoPEC device must also support its use in multi-SoPEC systems such as that shown in Figure 27. A SoPEC may be assigned any one of a number of identities in a multi-SoPEC system. A SoPEC may be one or more of a PrintMaster, a LineSyncMaster, an ISIMaster, a StorageSoPEC or an ISISlave SoPEC.

12.1.1.1 ISIMaster device

5

15

20

35

40

The ISIMaster is the only device that controls the common ISI lines (see Figure 30) and typically interfaces directly with the host. In most systems the ISIMaster will simply be the SoPEC connected to the USB bus. Future systems, however, may employ an ISI-Bridge chip to interface between the host and the ISI bus and in such systems the ISI-Bridge chip will be the ISIMaster. There can only be one ISIMaster on an ISI bus.

Systems with multiple SoPECs may have more than one host connection, for example there could be two SoPECs communicating with the external host over their FS USB links (this would of course require two USB cables to be connected), but still only one ISIMaster.

While it is not expected to be required, it is possible for a device to hand over its role as the ISIMaster to another device on the ISI i.e. the ISIMaster is not necessarily fixed.

12.1.1.2 PrintMaster device

The PrintMaster device is responsible for co-ordinating all aspects of the print operation. This includes starting the print operation in all printing SoPECs and communicating status back to the external host. When the ISIMaster is a SoPEC device it is also likely to be the PrintMaster as well. There may only be one PrintMaster in a system and it is most likely to be a SoPEC device.

12.1.1.3 LineSyncMaster device

The LineSyncMaster device generates the *Isync* pulse that all SoPECs in the system must synchronize their line outputs with. Any SoPEC in the system could act as a LineSyncMaster although the PrintMaster is probably the most likely candidate. It is possible that the LineSyncMaster may not be a SoPEC device at all - it could, for example, come from some OEM motor control circuitry. There may only be one LineSyncMaster in a system.

12.1.1.4 Storage device

For certain printer types it may be realistic to use one SoPEC as a storage device without using its

print engine capability - that is to effectively use it as an ISI-attached DRAM. A storage SoPEC
would receive data from the ISIMaster (most likely to be an ISI-Bridge chip) and then distribute it to
the other SoPECs as required. No other type of data flow (e.g. ISISlave -> storage SoPEC ->
ISISlave) would need to be supported in such a scenario. The SCB supports this functionality at no
additional cost because the CPU handles the task of transferring outbound data from the embedded

DRAM to the ISI transmit buffer. The CPU in a storage SoPEC will have almost nothing else to do.

12.1.1.5 ISISlave device

Multi-SoPEC systems will contain one or more ISISlave SoPECs. An ISISlave SoPEC is primarily used to generate dot data for the printhead IC it is driving. An ISISlave will not transmit messages on the ISI without first receiving permission to do so, via a ping packet (see section 12.4.4.6), from the ISIMaster

12.1.1.6 ISI-Bridge device

SoPEC is targeted at the low-cost small office / home office (SoHo) market. It may also be used in future systems that target different market segments which are likely to have a high speed interface capability. A future device, known as an ISI-Bridge chip, is envisaged which will feature both a high speed interface (such as High-Speed (HS) USB, Ethernet or IEEE1394) and one or more ISI

interfaces. The use of multiple ISI buses would allow the construction of independent print systems within the one printer. The ISI-Bridge would be the ISIMaster for each of the ISI buses it interfaces to.

12.1.1.7 External host

- The external host is most likely (but is not required) to be, a PC. Any system that can act as a USB host or that can interface to an ISI-Bridge chip could be the external host. In particular, with the development of USB On-The-Go (USB OTG), it is possible that a number of USB OTG enabled products such as PDAs or digital cameras will be able to directly interface with a SoPEC printer.
 - 12.1.1.8 External USB device
- The external USB device is most likely (but is not required) to be, a digital camera. Any system that can act as a USB device could be connected as an external USB device. This is to facilitate printing in the absence of a PC.
 - 12.1.2 Types of communication
 - 12.1.2.1 Communications with external host
- The external host communicates directly with the ISIMaster in order to print pages. When the ISIMaster is a SoPEC, the communications channel is FS USB.
 - 12.1.2.1.1 External host to ISIMaster communication

The external host will need to communicate the following information to the ISIMaster device:

- Communications channel configuration and maintenance information
- Most data destined for PrintMaster, ISISlave or storage SoPEC devices. This data is simply relayed by the ISIMaster
 - Mapping of virtual communications channels, such as USB endpoints, to ISI destination
 - 12.1.2.1.2 ISIMaster to external host communication

The ISIMaster will need to communicate the following information to the external host:

- Communications channel configuration and maintenance information
 - All data originating from the PrintMaster, ISISlave or storage SoPEC devices and destined for the external host. This data is simply relayed by the ISIMaster
 - 12.1.2.1.3 External host to PrintMaster communication

The external host will need to communicate the following information to the PrintMaster device:

- Program code for the PrintMaster
 - Compressed page data for the PrintMaster
 - Control messages to the PrintMaster
 - Tables and static data required for printing e.g. dead nozzle tables, dither matrices etc.
 - Authenticatable messages to upgrade the printer's capabilities
- 35 12.1.2.1.4 PrintMaster to external host communication

The PrintMaster will need to communicate the following information to the external host:

- Printer status information (i.e. authentication results, paper empty/jammed etc.)
- Dead nozzle information
- Memory buffer status information
- Power management status

- Encrypted SoPEC_id for use in the generation of PRINTER_QA keys during factory programming
- 12.1.2.1.5 External host to ISISlave communication

All communication between the external host and ISISlave SoPEC devices must be direct (via a dedicated connection between the external host and the ISISlave) or must take place via the ISIMaster. In the case of a SoPEC ISIMaster it is possible to configure each individual USB endpoint to act as a control channel to an ISISlave SoPEC if desired, although the endpoints will be more usually used to transport data. The external host will need to communicate the following information to ISISlave devices over the comms/ISI:

- 10 Program code for ISISIave SoPEC devices
 - Compressed page data for ISISlave SoPEC devices
 - Control messages to the ISISlave SoPEC (where a control channel is supported)
 - Tables and static data required for printing e.g. dead nozzle tables, dither matrices etc.
 - Authenticatable messages to upgrade the printer's capabilities
- 15 12.1.2.1.6 ISISlave to external host communication

All communication between the ISISlave SoPEC devices and the external host must take place via the ISIMaster. The ISISlave will need to communicate the following information to the external host over the comms/ISI:

- Responses to the external host's control messages (where a control channel is supported)
- Dead nozzle information from the ISISlave SoPEC.
 - Encrypted SoPEC_id for use in the generation of PRINTER_QA keys during factory programming
 - 12.1.2.2 Communication with external USB device
 - 12.1.2.2.1 ISIMaster to External USB device communication
- Communications channel configuration and maintenance information.
 - 12.1.2.2.2 External USB device to ISIMaster communication
 - Print data from a function on the external USB device.
 - 12.1.2.3 Communication over ISI
 - 12.1.2.3.1 ISIMaster to PrintMaster communication
- The ISIMaster and PrintMaster will often be the same physical device. When they are different devices then the following information needs to be exchanged over the ISI:
 - All data from the external host destined for the PrintMaster (see section 12.1.2.1.4).
 This data is simply relayed by the ISIMaster
 - 12.1.2.3.2 PrintMaster to ISIMaster communication
- The ISIMaster and PrintMaster will often be the same physical device. When they are different devices then the following information needs to be exchanged over the ISI:
 - All data from the PrintMaster destined for the external host (see section 12.1.2.1.4). This data is simply relayed by the ISIMaster
 - 12.1.2.3.3 ISIMaster to ISISlave communication
- 40 The ISIMaster may wish to communicate the following information to the ISISlaves:

- All data (including program code such as ISIId enumeration) originating from the external
 host and destined for the ISISlave (see section 12.1.2.1.5). This data is simply relayed by the
 ISIMaster
- wake up from sleep mode
- 5 12.1.2.3.4 ISISlave to ISIMaster communication

The ISISlave may wish to communicate the following information to the ISIMaster:

- All data originating from the ISISlave and destined for the external host (see section 12.1.2.1.6). This data is simply relayed by the ISIMaster
- 12.1.2.3.5 PrintMaster to ISISlave communication
- When the PrintMaster is not the ISIMaster all ISI communication is done in response to ISI ping packets (see 12.4.4.6). When the PrintMaster is the ISIMaster then it will of course communicate directly with the ISISlaves. The PrintMaster SoPEC may wish to communicate the following information to the ISISlaves:
 - Ink status e.g. requests for dotCount data i.e. the number of dots in each color fired by the printheads connected to the ISISlaves
 - configuration of GPIO ports e.g. for clutch control and lid open detect
 - power down command telling the ISISlave to enter sleep mode
 - ink cartridge fail information

15

20

This list is not complete and the time constraints associated with these requirements have yet to be determined.

In general the PrintMaster may need to be able to:

- send messages to an ISISlave which will cause the ISISlave to return the contents of ISISlave registers to the PrintMaster or
- to program ISISlave registers with values sent by the PrintMaster
- This should be under the control of software running on the CPU which writes messages to the ISI/SCB interface.
 - 12.1.2.3.6 ISISlave to PrintMaster communication

ISISlaves may need to communicate the following information to the PrintMaster:

- ink status e.g. *dotCount* data i.e. the number of dots in each color fired by the printheads connected to the ISISlaves
 - band related information e.g. finished band interrupts
 - page related information i.e. buffer underrun, page finished interrupts
 - MMU security violation interrupts
 - GPIO interrupts and status e.g. clutch control and lid open detect
- 35 printhead temperature
 - printhead dead nozzle information from SoPEC printhead nozzle tests
 - power management status

This list is not complete and the time constraints associated with these requirements have yet to be determined.

As the ISI is an insecure interface commands issued over the ISI should be of limited capability e.g. only limited register writes allowed. The software protocol needs to be constructed with this in mind. In general ISISlaves may need to return register or status messages to the PrintMaster or ISIMaster. They may also need to indicate to the PrintMaster or ISIMaster that a particular interrupt has occurred on the ISISlave. This should be under the control of software running on the CPU which writes messages to the ISI block.

12.1.2.3.7 ISISlave to ISISlave communication

The amount of information that will need to be communicated between ISISlaves will vary considerably depending on the printer configuration. In some systems ISISlave devices will only need to exchange small amounts of control information with each other while in other systems (such as those employing a storage SoPEC or extra USB connection) large amounts of compressed page data may be moved between ISISlaves. Scenarios where ISISlave to ISISlave communication is required include: (a) when the PrintMaster is not the ISIMaster, (b) QA Chip ink usage protocols, (c) data transmission from data storage SoPECs, (d) when there are multiple external host connections supplying data to the printer.

12.1.3 SCB Block Diagram

5

10

15

20

The SCB consists of four main sub-blocks, as shown in the basic block diagram of Figure 28.

12.1.4 Definitions of I/Os

The toplevel I/Os of the SCB are listed in Table 32. A more detailed description of their functionality will be given in the relevant sub-block sections.

Table 32. SCB I/O

Port name	s	1/0	Description
Clocks and Resets		1	
prst_n	1	ln	System reset signal. Active low.
Pclk	1	In	System clock.
usbclk	1	I n	48MHz clock for the USB device and host cores. The cores also require a 12MHz clock, which will be generated locally by dividing the 48MHz clock by 4.
isi_cpr_reset_n	1	Out	Signal from the ISI indicating that ISI activity has been detected while in sleep mode and so the chip should be reset. Active low.
usbd_cpr_reset_n	1	Out	Signal from the USB device that a USB reset has occurred. Active low.
USB device IO transceiver			
signals			
usbd_ts	1	Out	USB device IO transceiver (BUSB2_PM) driver three-state control. Active high enable.

usbd_a	1	Out	USB device IO transceiver (BUSB2_PM) driver
			data input.
usbd_se0	1	Out	USB device IO transceiver (BUSB2_PM)
			single-ended zero input. Active high.

	ļ		Bit 1 - USB Device interrupt
DIU interface		<u> </u>	
scb_diu_wadr[21:5]	17	Out	Write address bus to the DIU
scb_diu_data[63:0]	64	Out	Data bus to the DIU.
scb_diu_wreq	1	Out	Write request to the DIU
diu_scb_wack	1	ln	Acknowledge from the DIU that the write
			request was accepted.
scb_diu_wvalid	1	Out	Signal from the SCB to the DIU indicating that
			the data currently on the scb_diu_data[63:0]
	.		bus is valid
			

scb_diu_wmask[7:0]	7	Out	Byte aligned write mask. A "1" in a bit field of "scb_diu_wmask[7:0]" means that the corresponding byte will be written to DRAM.
scb_diu_rreq	1	Out	Read request to the DIU.
scb_diu_radr[21:5]	17	Out	Read address bus to the DIU
diu_scb_rack	1	In	Acknowledge from the DIU that the read request was accepted.
diu_scb_rvalid	1	In	Signal from the DIU to the SCB indicating that the data currently on the diu_data[63:0] bus is valid
diu_data[63:0]	64	ln	Common DIU data bus.
GPIO interface			
isi_gpio_dout[3:0]	4	Out	ISI output data to GPIO pins
isi_gpio_e[3:0]	4	Out	ISI output enable to GPIO pins
gpio_isi_din[3:0]	4	In	Input data from GPIO pins to ISI

12.1.5 SCB Data Flow

A logical view of the SCB is shown in Figure 29, depicting the transfer of data within the SCB.

- 12.2 USBD (USB DEVICE SUB-BLOCK)
- 12.2.1 Overview

10

15

20

The FS USB device controller core and associated SCB logic are referred to as the USB Device (USBD).

A SoPEC printer has FS USB device capability to facilitate communication between an external USB host and a SoPEC printer. The USBD is self-powered. It connects to an external USB host via a dedicated USB interface on the SoPEC printer, comprising a USB connector, the necessary discretes for USB signalling and the associated SoPEC ASIC I/Os.

The FS USB device core will be third party IP from Synopsys: TymeWareTM USB1.1 Device Controller (UDCVCI). Refer to the UDCVCI User Manual [20] for a description of the core. The device core does not support LS USB operation. Control and bulk transfers are supported by the device. Interrupt transfers are not considered necessary because the required interrupt-type

functionality can be achieved by sending query messages over the control channel on a scheduled basis. There is no requirement to support isochronous transfers.

The device core is configured to support 6 USB endpoints (EPs): the default control EP (EP0), 4 bulk OUT EPs (EP1, EP2, EP3, EP4) and 1 bulk IN EP (EP5). It should be noted that the direction of each EP is with respect to the USB host, i.e. *IN* refers to data transferred to the external host and *OUT* refers to data transferred from the external host. The 4 bulk OUT EPs will be used for the transfer of data from the external host to SoPEC, e.g. compressed page data, program data or control messages. Each bulk OUT EP can be mapped on to any target destination in a multi-SoPEC system, via the SCB Map configuration registers. The bulk IN EP is used for the transfer of data from SoPEC to the external host, e.g. a print image downloaded from a digital camera that requires

processing on the external host system. Any feedback data will be returned to the external host on EP0, e.g. status information.

The device core does not provide internal buffering for any of its EPs (with the exception of the 8 byte setup data payload for control transfers). All EP buffers are provided in the SCB. Buffers will be grouped according to EP direction and associated packet destination. The SCB Map configuration registers contain a *DestISIId* and *DestISISubId* for each OUT EP, defining their EP mapping and therefore their packet destination. Refer to section Section 12.4 ISI (Inter SoPEC Interface Subblock) for further details on *ISIId* and *ISISubId*. Refer to section Section 12.5 CTRL (Control Subblock) for further details on the mapping of OUT EPs.

10 12.2.2 USBD effective bandwidth

5

20

30

35

The effective bandwidth between an external USB host and the printer will be influenced by:

- Amount of activity from other devices that share the USB with the printer.
- Throughput of the device controller core.
- EP buffering implementation.
- Responsiveness of the external host system CPU in handling USB interrupts.

To maximize bandwidth to the printer it is recommended that no other devices are active on the USB between the printer and the external host. If the printer is connected to a HS USB external host or hub it may limit the bandwidth available to other devices connected to the same hub but it would not significantly affect the bandwidth available to other devices upstream of the hub. The EP buffering should not limit the USB device core throughput, under normal operating conditions. Used in the recommended configuration, under ideal operating conditions, it is expected that an effective bandwidth of 8-9 Mbit/s will be achieved with bulk transfers between the external host and the printer.

12.2.3 IN EP packet buffer

The IN EP packet buffer stores packets originating from the LEON CPU that are destined for transmission over the USB to the external USB host. CPU writes to the buffer are 32 bits wide. USB device core reads from the buffer 32 bits wide.

128 bytes of local memory are required in total for EP0-IN and EP5-IN buffering. The IN EP buffer is a single, 2-port local memory instance, with a dedicated read port and a dedicated write port. Both ports are 32 bits wide. Each IN EP has a dedicated 64 byte packet location available in the memory array to buffer a single USB packet (maximum USB packet size is 64 bytes). Each individual 64 byte packet location is structured as 16 x 32 bit words and is read/written in a FIFO manner. When the device core reads a packet entry from the IN EP packet buffer, the buffer must retain the packet until the device core performs a status write, informing the SCB that the packet has been accepted by the external USB host and can be flushed. The CPU can therefore only write a single packet at a time to each IN EP. Any subsequent CPU write request to a buffer location containing a valid packet will be refused, until that packet has been successfully transmitted.

12.2.4 OUT EP packet buffer

The OUT EP packet buffer stores packets originating from the external USB host that are destined for transmission over DMAChannel0, DMAChannel1 or the ISI. The SCB control logic is responsible

for routing the OUT EP packets from the OUT EP packet buffer to DMA or to the ISITx Buffer, based on the SCB Map configuration register settings. USB core writes to the buffer are 32 bits wide. DMA and ISI associated reads from the buffer are both 64 bits wide.

512 bytes of local memory are required in total for EP0-OUT, EP1-OUT, EP2-OUT, EP3-OUT and EP4-OUT buffering. The OUT EP packet buffer is a single, 2-port local memory instance, with a dedicated read port and a dedicated write port. Both ports are 64 bits wide. Byte enables are used for the 32 bit wide USB device core writes to the buffer. Each OUT EP can be mapped to DMAChannel0, DMAChannel1 or the ISI.

The OUT EP packet buffer is partitioned accordingly, resulting in three distinct packet FIFOs:

- USBDDMA0FIFO, for USB packets destined for DMAChannel0 on the local SoPEC.
 - USBDDMA1FIFO, for USB packets destined for DMAChannel1 on the local SoPEC.
 - USBDISIFIFO, for USB packets destined for transmission over the ISI.

12.2.4.1 USBDDMAnFIFO

5

This description applies to USBDDMA0FIFO and USBDDMA1FIFO, where 'n' represents the respective DMA channel, i.e. n=0 for USBDDMA0FIFO, n=1 for USBDDMA1FIFO.

USBDDMAnFIFO services any EPs mapped to DMAChanneln on the local SoPEC device. This implies that a packet originating from an EP with an associated ISIId that matches the local SoPEC ISIId and an ISISubId=n will be written to USBDDMAnFIFO, if there is space available for that packet.

- USBDDMAnFIFO has a capacity of 2 x 64 byte packet entries, and can therefore buffer up to 2 USB packets. It can be considered as a 2 packet entry FIFO. Packets will be read from it in the same order in which they were written, i.e. the first packet written will be the first packet read and the second packet written will be the second packet read. Each individual 64 byte packet location is structured as 8 x 64 bit words and is read/written in a FIFO manner.
- The USBDDMAnFIFO has a write granularity of 64 bytes, to allow for the maximum USB packet size. The USBDDMAnFIFO will have a read granularity of 32 bytes to allow for the DMA write access bursts of 4 x 64 bit words, i.e. the DMA Manager will read 32 byte chunks at a time from the USBDDMAnFIFO 64byte packet entries, for transfer to the DIU.
- It is conceivable that a packet which is not a multiple 32 bytes in size may be written to the

 USBDDMAnFIFO. When this event occurs, the DMA Manager will read the contents of the
 remaining address locations associated with the 32 byte chunk in the USBDDMAnFIFO, transferring
 the packet plus whatever data is present in those locations, resulting in a 32 byte packet (a burst of
 4 x 64 bit words) transfer to the DIU.
- The DMA channels should achieve an effective bandwidth of 160 Mbits/sec (1 bit/cycle) and should never become blocked, under normal operating conditions. As the USB bandwidth is considerably less, a 2 entry packet FIFO for each DMA channel should be sufficient.

12.2.4.2 USBDISIFIFO

40

USBDISIFIFO services any EPs mapped to ISI. This implies that a packet originating from an EP with an associated *ISIId* that does not match the local SoPEC *ISIId* will be written to USBDISIFIFO if there is space available for that packet.

USBDISIFIFO has a capacity of 4 x 64 byte packet entries, and can therefore buffer up to 4 USB packets. It can be considered as a 4 packet entry FIFO. Packets will be read from it in the same order in which they were written, i.e. the first packet written will be the first packet read and the second packet written will be the second packet read, etc. Each individual 64 byte packet location is structured as 8×64 bit words and is read/written in a FIFO manner.

The ISI long packet format will be used to transfer data across the ISI. Each ISI long packet data payload is 32 bytes. The USBDISIFIFO has a write granularity of 64 bytes, to allow for the maximum USB packet size. The USBDISIFIFO will have a read granularity of 32 bytes to allow for the ISI packet size, i.e. the SCB will read 32 byte chunks at a time from the USBDISIFIFO 64byte packet entries, for transfer to the ISI.

It is conceivable that a packet which is not a multiple 32 bytes in size may be written to the USBDISIFIFO, either intentionally or due to a software error. A maskable interrupt per EP is provided to flag this event. There will be 2 options for dealing with this scenario on a per EP basis:

Discard the packet.

5

10

20

25

30

35

• Read the contents of the remaining address locations associated with the 32 byte chunk in the USBDISIFIFO, transferring the irregular size packet plus whatever data is present in those locations, resulting in a 32 byte packet transfer to the *ISITxBuffer*.

The ISI should achieve an effective bandwidth of 100 Mbits/sec (4 wire configuration). It is possible to encounter a number of retries when transmitting an ISI packet and the LEON CPU will require access to the ISI transmit buffer. However, considering the relatively low bandwidth of the USB, a 4 packet entry FIFO should be sufficient.

12.2.5 Wake-up from sleep mode

The SoPEC will be placed in sleep mode after a suspend command is received by the USB device core. The USB device core will continue to be powered and clocked in sleep mode. A USB reset, as opposed to a device resume, will be required to bring SoPEC out of its sleep state as the sleep state is hoped to be logically equivalent to the power down state.

The USB reset signal originating from the USB controller will be propagated to the CPR (as $usb_cpr_reset_n$) if the USBWakeupEnable bit of the WakeupEnable register (see Table) has been set. The USBWakeupEnable bit should therefore be set just prior to entering sleep mode.

There is a scenario that would require SoPEC to initiate a USB remote wake-up (i.e. where SoPEC signals resume to the external USB host after being suspended by the external USB host). A digital camera (or other supported external USB device) could be connected to SoPEC via the internal SoPEC USB host controller core interface. There may be a need to transfer data from this external USB device, via SoPEC, to the external USB host system for processing. If the USB connecting the external host system and SoPEC was suspended, then SoPEC would need to initiate a USB remote wake-up.

- 12.2.6.5 OUT EP Buffer
- 5 12.3 USBH (USB HOST SUB-BLOCK)
 - 12.3.1 Overview

20

25

30

The SoPEC USB Host Controller (HC) core, associated SCB logic and associated SoPEC ASIC I/Os are referred to as the USB Host (USBH).

A SoPEC printer has FS USB host capability, to facilitate communication between an external USB device and a SoPEC printer. The USBH connects to an external USB device via a dedicated USB interface on the SoPEC printer, comprising a USB connector, the necessary discretes for USB signalling and the associated SoPEC ASIC I/Os.

The FS USB HC core are third party IP from Synopsys: DesignWare^R USB1.1 OHCI Host Controller with PVCI (UHOSTC_PVCI). Refer to the UHOSTC_PVCI User Manual [18] for details of the core.

Refer to the Open Host Controller Interface (OHCI) Specification Release [19] for details of OHCI operation.

The HC core supports Low-Speed (LS) USB devices, although compatible external USB devices are most likely to be FS devices. It is expected that communication between an external USB device and a SoPEC printer will be achieved with control and bulk transfers. However, isochronous and interrupt transfers are also supported by the HC core.

There will be 2 communication channels between the Host Controller Driver (HCD) software running on the LEON CPU and the HC core:

- OHCI operational registers in the HC core. These registers are control, status, list pointers
 and a pointer to the Host Controller Communications Area (HCCA) in shared memory. A
 target Peripheral Virtual Component Interface (PCVI) on the HC core will provide LEON with
 direct read/write access to the operational registers. Refer to the OHCI Specification for
 details of these registers.
- HCCA in SoPEC eDRAM. An initiator Peripheral Virtual Component Interface
 (PCVI) on the HC core will provide the HC with DMA read/write access to an address space in
 eDRAM. The HCD running on LEON will have read/write access to the same address space. Refer
 to the OHCI Specification for details of the HCCA.

The target PVCI interface is a 32 bit word aligned interface, with byte enables for write access. All read/ write access to the target PVCI interface by the LEON CPU will be 32 bit word aligned. The byte enables will not be used, as all registers will be read and written as 32 bit words.

- The initiator PVCI interface is a 32 bit word aligned interface with byte enables for write access. All DMA read/write accesses are 256 bit word aligned, in bursts of 4 x 64 bit words. As there is no guarantee that the read/write requests from the HC core will start at a 256 bit boundary or be 256 bits long, it is necessary to provide 8 byte enables for each of the 64 bit words in a write burst form the HC core to DMA. The signal *scb_diu_wmask* serves this purpose.
- 40 Configuration of the HC core will be performed by the HCD.

12.3.2 Read/Write Buffering

5

The HC core maximum burst size for a read/write access is 4 x 32 bit words. This implies that the minimum buffering requirements for the HC core will be a 1 entry deep address register and a 4 entry deep data register. It will be necessary to provide data and address mapping functionality to convert the 4 x 32 bit word HC core read/write bursts into 4 x 64 bit word DMA read/write bursts. This will meet the minimum buffering requirements.

12.3.3 USBH effective bandwidth

The effective bandwidth between an external USB device and a SoPEC printer will be influenced by:

- Amount of activity from other devices that share the USB with the external USB device.
 - Throughput of the HC core.
 - HC read/write buffering implementation.
 - Responsiveness of the LEON CPU in handling USB interrupts.

Effective bandwidth between an external USB device and a SoPEC printer is not an issue. The
primary application of this connectivity is the download of a print image from a digital camera.
Printing speed is not important for this type of print operation. However, to maximize bandwidth to
the printer it is recommended that no other devices are active on the USB between the printer and
the external USB device. The HC read/write buffering in the SCB should not limit the USB HC core
throughput, under normal operating conditions.

- Used in the recommended configuration, under ideal operating conditions, it is expected that an effective bandwidth of 8-9 Mbit/s will be achieved with bulk transfers between the external USB device and the SoPEC printer.

 - 12.3.5.1 USB Host IP Core
 - 12.3.5.2 PVCI Target
 - 12.3.5.3 PVCI Initiator
- 30 12.3.5.4 Read/Write Buffer
 - 12.4 ISI (INTER SOPEC INTERFACE SUB-BLOCK)
 - 12.4.1 Overview

35

40

The ISI is utilised in all system configurations requiring more than one SoPEC. An example of such a system which requires four SoPECs for duplex A3 printing and an additional SoPEC used as a storage device is shown in Figure 27.

The ISI performs much the same function between an ISISlave SoPEC and the ISIMaster as the USB connection performs between the ISIMaster and the external host. This includes the transfer of all program data, compressed page data and message (i.e. commands or status information) passing between the ISIMaster and the ISISlave SoPECs. The ISIMaster initiates all communication with the ISISlaves.

12.4.2 ISI Effective Bandwidth

5

10

15

20

35

40

The ISI will need to run at a speed that will allow error free transmission on the PCB while minimising the buffering and hardware requirements on SoPEC. While an ISI speed of 10 Mbit/s is adequate to match the effective FS USB bandwidth it would limit the system performance when a high-speed connection (e.g. USB2.0, IEEE1394) is used to attach the printer to the PC. Although they would require the use of an extra ISI-Bridge chip such systems are envisaged for more expensive printers (compared to the low-cost basic SoPEC powered printers that are initially being targeted) in the future.

An ISI line speed (i.e. the speed of each individual ISI wire) of 32 Mbit/s is therefore proposed as it will allow ISI data to be over-sampled 5 times (at a *pclk* frequency of 160MHz). The total bandwidth of the ISI will depend on the number of pins used to implement the interface. The ISI protocol will work equally well if 2 or 4 pins are used for transmission/reception. The *ISINumPins* register is used to select between a 2 or 4 wire ISI, giving peak raw bandwidths of 64 Mbit/s and 128 Mbit/s respectively. Using either a 2 or 4 wire ISI solution would allow the movement of data in to and out of a storage SoPEC (as described in 12.1.1.4 above), which is the most bandwidth hungry ISI use, in a timely fashion.

The *ISINumPins* register is used to select between a 2 or 4 wire ISI. A 2 wire ISI is the default setting for *ISINumPins* and this may be changed to a 4 wire ISI after initial communication has been established between the ISIMaster and all ISISlaves. Software needs to ensure that the switch from 2 to 4 wires is handled in a controlled and coordinated fashion so that nothing is transmitted on the ISI during the switch over period.

The maximum effective bandwidth of a two wire ISI, after allowing for protocol overheads and bus turnaround times, is expected to be approx. 50 Mbit/s.

12.4.3 ISI Device Identification and Enumeration

The ISIMasterSel bit of the ISICntrl register (see section Table) determines whether a SoPEC is an ISIMaster (ISIMasterSel = 1), or an ISISlave (ISIMasterSel = 0).

SoPEC defaults to being an ISISlave (ISIMasterSel = 0) after a power-on reset - i.e. it will not transmit data on the ISI without first receiving a ping. If a SoPEC's ISIMasterSel bit is changed to 1, then that SoPEC will become the ISIMaster, transmitting data without requiring a ping, and generating pings as appropriately programmed.

ISIMasterSel can be set to 1 explicitly by the CPU writing directly to the ISICntrl register.

ISIMasterSel can also be automatically set to 1 when activity occurs on any of USB endpoints 2-4 and the AutoMasterEnable bit of the ISICntrl register is also 1 (the default reset condition). Note that if AutoMasterEnable is 0, then activity on USB endpoints 2-4 will not result in ISIMasterSel being set to 1. USB endpoints 2-4 are chosen for the automatic detection since the power-on-reset condition has USB endpoints 0 and 1 pointing to ISIId 0 (which matches the local SoPEC's ISIId after power-on reset). Thus any transmission on USB endpoints 2-4 indicate a desire to transmit on the ISI which would usually indicate ISIMaster status. The automatic setting of ISIMasterSel can be disabled by clearing AutoMasterEnable, thereby allowing the SoPEC to remain an ISISlave while still making use of the USB endpoints 2-4 as external destinations.

Thus the setting of a SoPEC being ISIMaster or ISISlave can be completely under software control, or can be completely automatic.

The ISIId is established by software downloaded over the ISI (in broadcast mode) which looks at the input levels on a number of GPIO pins to determine the ISIId. For any given printer that uses a multi-SoPEC configuration it is expected that there will always be enough free GPIO pins on the ISISlaves to support this enumeration mechanism.

12.4.4 ISI protocol

5

10

15

20

25

30

35

40

The ISI is a serial interface utilizing a 2/4 wire half-duplex configuration such as the 2-wire system shown in Figure 30 below. An ISIMaster must always be present and a variable number of ISISlaves may also be on the ISI bus. The ISI protocol supports up to 14 addressable slaves, however to simplify electrical issues the ISI drivers need only allow for 5-6 ISI devices on a particular ISI bus. The ISI bus enables broadcasting of data, ISIMaster to ISISlave communication, ISISlave to ISIMaster communication and ISISlave to ISISlave communication. Flow control, error detection and retransmission of errored packets is also supported. ISI transmission is asynchronous and a *Start* field is present in every transmitted packet to ensure synchronization for the duration of the packet.

To maximize the effective ISI bandwidth while minimising pin requirements a half-duplex interleaved transmission scheme is used. Figure 31 below shows how a 16-bit word is transmitted from an ISIMaster to an ISISlave over a 2-wire ISI bus. Since data will be interleaved over the wires and a 4-wire ISI is also supported, all ISI packets should be a multiple of 4 bits.

All ISI transactions are initiated by the ISIMaster and every non-broadcast data packet needs to be acknowledged by the addressed recipient. An ISISlave may only transmit when it receives a ping packet (see section 12.4.4.6) addressed to it. To avoid bus contention all ISI devices must wait *ISITurnAround* bit-times (5 *pclk* cycles per bit) after detecting the end of a packet before transmitting a packet (assuming they are required to transmit). All non-transmitting ISI devices must tristate their Tx drivers to avoid line contention. The ISI protocol is defined to avoid devices driving out of order (e.g. when an ISISlave is no longer being addressed). As the ISI uses standard I/O pads there is no physical collision detection mechanism.

There are three types of ISI packet: a long packet (used for data transmission), a ping packet (used by the ISIMaster to prompt ISISlaves for packets) and a short packet (used to acknowledge receipt of a packet). All ISI packets are delineated by a *Start* and *Stop* fields and transmission is atomic i.e. an ISI packet may not be split or halted once transmission has started.

12.4.4.1 ISI transactions

The different types of ISI transactions are outlined in Figure 32 below. As described later all NAKs are inferred and ACKs are not addressed to any particular ISI device.

12.4.4.2 Start Field Description

The Start field serves two purposes: To allow the start of a packet be unambiguously identified and to allow the receiving device synchronise to the data stream. The symbol, or data value, used to identify a Start field must not legitimately occur in the ensuing packet. Bit stuffing is used to guarantee that the Start symbol will be unique in any valid (i.e. error free) packet. The ISI needs to

see a valid Start symbol before packet reception can commence i.e. the receive logic constantly looks for a *Start* symbol in the incoming data and will reject all data until it sees a *Start* symbol. Furthermore if a *Start* symbol occurs (incorrectly) during a data packet it will be treated as the start of a new packet. In this case the partially received packet will be discarded.

The data value of the *Start* symbol should guarantee that an adequate number of transitions occur on the physical ISI lines to allow the receiving ISI device to determine the best sampling window for the transmitted data. The *Start* symbol should also be sufficiently long to ensure that the bit stuffing overhead is low but should still be short enough to reduce its own contribution to the packet overhead. A *Start* symbol of b01010101 is therefore used as it is an effective compromise between these constraints.

Each SoPEC in a multi-SoPEC system will derive its system clock from a unique (i.e. one per SoPEC) crystal. The system clocks of each device will drift relative to each other over any period of time. The system clocks are used for generation and sampling of the ISI data. Therefore the sampling window can drift and could result in incorrect data values being sampled at a later point in time. To overcome this problem the ISI receive circuitry tracks the sampling window against the incoming data to ensure that the data is sampled in the centre of the bit period.

12.4.4.3 Stop Field Description

A 1 bit-time *Stop* field of b1 per ISI line ensures that all ISI lines return to the high state before the next packet is transmitted. The stop field is driven on to each ISI line simultaneously, i.e. b11 for a 2-wire ISI and b1111 for a 4-wire ISI would be interleaved over the respective ISI lines. Each ISI line is driven high for 1 bit-time. This is necessary because the first bit of the *Start* field is b0.

12.4.4.4 Bit Stuffing

15

20

30

35

This involves the insertion of bits into the bitstream at the transmitting SoPEC to avoid certain data patterns. The receiving SoPEC will strip these inserted bits from the bitstream.

Bit-stuffing will be performed when the *Start* symbol appears at a location other than the start field of any packet, i.e. when the bit pattern b0101010 occurs at the transmitter, a 0 will be inserted to escape the *Start* symbol, resulting in the bit pattern b01010100. Conversely, when the bit pattern b0101010 occurs at the receiver, if the next bit is a '0' it will be stripped, if it is a '1' then a *Start* symbol is detected.

If the frequency variations in the quartz crystal were large enough, it is conceivable that the resultant frequency drift over a large number of consecutive 1s or 0s could cause the receiving SoPEC to loose synchronisation.⁶ The quartz crystal that will be used in SoPEC systems is rated for 32MHz @ 100ppm. In a multi-SoPEC system with a 32MHz+100ppm crystal and a 32MHz-100ppm crystal, it would take approximately 5000 *pclk* cycles to cause a drift of 1 pclk cycle. This means that we would only need to bit-stuff somewhere before 1000 ISI bits of consecutive 1s or consecutive 0s, to ensure adequate

⁶Current max packet size ~= 290 bits = 145 bits per ISI line (on a 2 wire ISI) = 725 160MHz cycles. Thus the pclks in the two communicating ISI devices should not drift by more than one cycle in 725 i.e. 1379 ppm. Careful analysis of the crystal, PLL and oscillator specs and the sync detection circuit is needed here to ensure our solution is robust.

synchronization. As the maximum number of bits transmitted per ISI line in a packet is 145, it should not be necessary to perform bit-stuffing for consecutive 1s or 0s. We may wish to constrain the spec of *xtalin* and also *xtalin* for the ISI-Bridge chip to ensure the ISI cannot drift out of sync during packet reception.

Note that any violation of bit stuffing will result in the *RxFrameErrorSticky* status bit being set and the incoming packet will be treated as an errored packet.

12.4.4.5 ISI Long Packet

5

10

15

20

25

The format of a long ISI packet is shown in Figure 33 below. Data may only be transferred between ISI devices using a long packet as both the short and ping packets have no payload field. Except in the case of a broadcast packet, the receiving ISI device will always reply to a long packet with an explicit ACK (if no error is detected in the received packet) or will not reply at all (e.g. an error is detected in the received packet), leaving the transmitter to infer a NAK. As with all ISI packets the bitstream of a long packet is transmitted with its Isb (the leftmost bit in Figure 33) first. Note that the total length (in bits) of an ISI long packet differs slightly between a 2 and 4-wire ISI system due to the different number of bits required for the *Start* and *Stop* fields.

All long packets begin with the *Start* field as described earlier. The *PktDesc* field is described in Table 33.

Table 33. PktDesc field description

Bit	Description
0:1	00 - Long packet
	01 - Reserved
	10 - Ping packet
	11 – Reserved
2	Sequence bit value. Only valid for long packets. See section 12.4.4.9 for a description
	of sequence bit operation

Any ISI device in the system may transmit a long packet but only the ISIMaster may initiate an ISI transaction using a long packet. An ISISlave may only send a long packet in reply to a ping message from the ISIMaster. A long packet from an ISISlave may be addressed to any ISI device in the system.

The *Address* field is straightforward and complies with the ISI naming convention described in section 12.5.

The payload field is exactly what is in the transmit buffer of the transmitting ISI device and gets copied into the receive buffer of the addressed ISI device(s). When present the payload field is always 256 bits.

To ensure strong error detection a 16-bit CRC is appended.

12.4.4.6 ISI Ping Packet

The ISI ping packet is used to allow ISISlaves to transmit on the ISI bus. As can be seen from

Figure 34 below the ping packet can be viewed as a special case of the long packet. In other words it is a long packet without any payload. Therefore the *PktDesc* field is the same as a long packet *PktDesc*, with the exception of the sequence bit, which is not valid for a ping packet. Both the *ISISubId* and the sequence bit are fixed at 1 for all ping packets. These values were chosen to

maximize the hamming distance from an ACK symbol and to minimize the likelihood of bit stuffing. The *ISISubId* is unused in ping packets because the ISIMaster is addressing the ISI device rather than one of the DMA channels in the device. The ISISlave may address any *ISIId.ISISubId* in response if it wishes. The ISISlave will respond to a ping packet with either an explicit ACK (if it has nothing to send), an inferred NAK (if it detected an error in the ping packet) or a long packet (containing the data it wishes to send). Note that inferred NAKs do not result in the retransmission of a ping packet. This is because the ping packet will be retransmitted on a predetermined schedule (see 12.4.4.11 for more details).

An ISISlave should never respond to a ping message to the broadcast *ISIId* as this must have been sent in error. An ISI ping packet will never be sent in response to any packet and may only originate from an ISIMaster.

12.4.4.7 ISI Short Packet

The ISI short packet is only 17 bits long, including the *Start* and *Stop* fields. A value of b11101011 is proposed for the ACK symbol. As a 16-bit CRC is inappropriate for such a short packet it is not used. In fact there is only one valid value for a short ACK packet as the *Start*, ACK and *Stop* symbols all have fixed values. Short packets are only used for acknowledgements (i.e. explicit ACKs). The format of a short ISI packet is shown in Figure 35 below. The ACK value is chosen to ensure that no bit stuffing is required in the packet and to minimize its hamming distance from ping and long ISI packets.

20

5

10

15

12.4.4.8 Error Detection and Retransmission

The 16-bit CRC will provide a high degree of error detection and the probability of transmission errors occurring is very low as the transmission channel (i.e. PCB traces) will have a low inherent bit error rate. The number of undetected errors should therefore be minute.

- The HDLC standard CRC-16 (i.e. $G(x) = x^{16} + x^{12} + x^5 + 1$) is to be used for this calculation, which is to be performed serially. It is calculated over the entire packet (excluding the *Start* and *Stop* fields). A simple retransmission mechanism frees the CPU from getting involved in error recovery for most errors because the probability of a transmission error occurring more than once in succession is very, very low in normal circumstances.
- After each non-short ISI packet is transmitted the transmitting device will open a reply window. The size of the reply window will be *ISIShortReplyWin* bit times when a short packet is expected in reply, i.e. the size of a short packet, allowing for worst case bit stuffing, bus turnarounds and timing differences. The size of the reply window will be *ISILongReplyWin* bit times when a long packet is expected in reply, i.e. this will be the max size of a long packet, allowing for worst case bit stuffing, bus turnarounds and timing differences. In both cases if an ACK is received the window will close and another packet can be transmitted but if an ACK is not received then the full length of the window must be waited out.

As no reply should be sent to a broadcast packet, no reply window should be required however all other long packets open a reply window in anticipation of an ACK. While the desire is to minimize

the time between broadcast transmissions the simplest solution should be employed. This would imply the same size reply window as other long packets.

When a packet has been received without any errors the receiving ISI device must transmit its acknowledge packet (which may be either a long or short packet) before the reply window closes.

5 When detected errors do occur the receiving ISI device will not send any response. The transmitting ISI device interprets this lack of response as a NAK indicating that errors were detected in the transmitted packet or that the receiving device was unable to receive the packet for some reason (e.g. its buffers are full). If a long packet was transmitted the transmitting ISI device will keep the transmitted packet in its transmit buffer for retransmission. If the transmitting device is the ISIMaster 10 it will retransmit the packet immediately while if the transmitting device is an ISISlave it will

retransmit the packet in response to the next ping it receives from the ISIMaster.

The transmitting ISI device will continue retransmitting the packet when it receives a NAK until it either receives an ACK or the number of retransmission attempts equals the value of the NumRetries register. If the transmission was unsuccessful then the transmitting device sets the TxErrorSticky bit in its ISIIntStatus register. The receiving device also sets the RxErrorSticky bit in its ISIIntStatus register whenever it detects a CRC error in an incoming packet and is not required to take any further action, as it is up to the transmitting device to detect and rectify the problem. The NumRetries registers in all ISI devices should be set to the same value for consistent operation. Note that successful transmission or reception of ping packets do not affect retransmission

20 operation.

15

Note that a transmit error will cause the ISI to stop transmitting. CPU intervention will be required to resolve the source of the problem and to restart the ISI transmit operation. Receive errors however do not affect receive operation and they are collected to facilitate problem debug and to monitor the quality of the ISI physical channel. Transmit or receive errors should be extremely rare and their

25 occurrence will most likely indicate a serious problem.

> Note that broadcast packets are never acknowledged to avoid contention on the common ISI lines. If an ISISlave detects an error in a broadcast packet it should use the message passing mechanism described earlier to alert the ISIMaster to the error if it so wishes.

12.4.4.9 Sequence Bit Operation

30 To ensure that communication between transmitting and receiving ISI devices is correctly ordered a sequence bit is included in every long packet to keep both devices in step with each other. The sequence bit field is a constant for short or ping packets as they are not used for data transmission. In addition to the transmitted sequence bit all ISI devices keep two local sequence bits, one for each ISISubId. Furthermore each ISI device maintains a transmit sequence bit for each ISIId and 35 ISISubId it is in communication with. For packets sourced from the external host (via USB) the transmit sequence bit is contained in the relevant USBEPnDest register while for packets sourced from the CPU the transmit sequence bit is contained in the CPUISITxBuffCntrl register. The sequence bits for received packets are stored in ISISubId0Seq and ISISubId1Seq registers. All ISI devices will initialize their sequence bits to 0 after reset. It is the responsibility of software to ensure

that the sequence bits of the transmitting and receiving ISI devices are correctly initialized each time a new source is selected for any *ISIId.ISISubId* channel.

Sequence bits are ignored by the receiving ISI device for broadcast packets. However the broadcasting ISI device is free to toggle the sequence in the broadcast packets since they will not affect operation. The SCB will do this for all USB source data so that there is no special treatment for the sequence bit of a broadcast packet in the transmitting device. CPU sourced broadcasts will have sequence bits toggled at the discretion of the program code.

Each SoPEC may also ignore the sequence bit on either of its ISISubId channels by setting the appropriate bit in the *ISISubIdSeqMask* register. The sequence bit should be ignored for ISISubId channels that will carry data that can originate from more than one source and is self ordering e.g. control messages.

A receiving ISI device will toggle its sequence bit addressed by the ISISubId only when the receiver is able to accept data and receives an error-free data packet addressed to it. The transmitting ISI device will toggle its sequence bit for that ISIId.ISISubId channel only when it receives a valid ACK handshake from the addressed ISI device.

Figure 36 shows the transmission of two long packets with the sequence bit in both the transmitting and receiving devices toggling from 0 to 1 and back to 0 again. The toggling operation will continue in this manner in every subsequent transmission until an error condition is encountered.

When the receiving ISI device detects an error in the transmitted long packet or is unable to accept the packet (because of full buffers for example) it will not return any packet and it will not toggle its local sequence bit. An example of this is depicted in Figure 37. The absence of any response prompts the transmitting device to retransmit the original (seq=0) packet. This time the packet is received without any errors (or buffer space may have been freed) so the receiving ISI device toggles its local sequence bit and responds with an ACK. The transmitting device then toggles its local sequence bit to a 1 upon correct receipt of the ACK.

However it is also possible for the ACK packet from the receiving ISI device to be corrupted and this scenario is shown in Figure 38. In this case the receiving device toggles its local sequence bit to 1 when the long packet is received without error and replies with an ACK to the transmitting device. The transmitting device does not receive the ACK correctly and so does not change its local sequence bit. It then retransmits the seq=0 long packet. When the receiving device finds that there is a mismatch between the transmitted sequence bit and the expected (local) sequence bit is discards the long packet and replies with an ACK. When the transmitting ISI device correctly receives the ACK it updates its local sequence bit to a 1, thus restoring synchronization. Note that when the ISISubIdSeqMask bit for the addressed ISISubId is set then the retransmitted packet is not discarded and so a duplicate packet will be received. The data contained in the packet should be self-ordering and so the software handling these packets (most likely control messages) is expected to deal with this eventuality.

40 12.4.4.10 Flow Control

5

10

15

30

35

The ISI also supports flow control by treating it in exactly the same manner as an error in the received packet. Because the SCB enjoys greater guaranteed bandwidth to DRAM than both the ISI and USB can supply flow control should not be required during normal operation. Any blockage on a DMA channel will soon result in the NumRetries value being exceeded and transmission from that SoPEC being halted. If a SoPEC NAKs a packet because its RxBuffer is full it will flag an overflow condition. This condition can potentially cause a CPU interrupt, if the corresponding interrupt is enabled. The RxOverflowSticky bit of its ISIIntStatus register reflects this condition. Because flow control is treated in the same manner as an error the transmitting ISI device will not be able to differentiate a flow control condition from an error in the transmitted packet.

10 12.4.4.11 Auto-ping Operation

5

15

20

25

30

35

40

While the CPU of the ISIMaster could send a ping packet by writing the appropriate header to the CPUISITxBuffCntrl register it is expected that all ping packets will be generated in the ISI itself. The use of automatically generated ping packets ensures that ISISlaves will be given access to the ISI bus with a programmable minimum guaranteed frequency in addition to whenever it would otherwise be idle. Five registers facilitate the automatic generation of ping messages within the ISI: PingSchedule0, PingSchedule1, PingSchedule2, ISITotalPeriod and ISILocalPeriod. Auto-pinging will be enabled if any bit of any of the PingScheduleN registers is set and disabled if all PingScheduleN registers are 0x0000.

Each bit of the 15-bit PingScheduleN register corresponds to an ISIId that is used in the Address field of the ping packet and a 1 in the bit position indicates that a ping packet is to be generated for that ISIId. A 0 in any bit position will ensure that no ping packet is generated for that ISIId. As ISISlaves may differ in their bandwidth requirement (particularly if a storage SoPEC is present) three different PingSchedule registers are used to allow an ISISlave receive up to three times the number of pings as another active ISISlave. When the ISIMaster is not sending long packets (sourced from either the CPU or USB in the case of a SoPEC ISIMaster) ISI ping packets will be transmitted according to the pattern given by the three PingScheduleN registers. The ISI will start with the lsb of PingSchedule0 register and work its way from lsb through msb of each of the PingScheduleN registers. When the msb of PingSchedule2 is reached the ISI returns to the Isb of PingSchedule0 and continues to cycle through each bit position of each PingScheduleN register. The ISI has more than enough time to work out the destination of the next ping packet while a ping

or long packet is being transmitted.

With the addition of auto-ping operation we now have three potential sources of packets in an ISIMaster SoPEC: USB, CPU and auto-ping. Arbitration between the CPU and USB for access to the ISI is handled outside the ISI. To ensure that local packets get priority whenever possible and that ping packets can have some guaranteed access to the ISI we use two 4-bit counters whose reload value is contained in the ISITotalPeriod and ISILocalPeriod registers. As we saw in section 12.4.4.1 every ISI transaction is initiated by the ISIMaster transmitting either a long packet or a ping packet. The ISITotalPeriod counter is decremented for every ISI transaction (i.e. either long or ping) when its value is non-zero. The ISILocalPeriod counter is decremented for every local packet that is transmitted. Neither counter is decremented by a retransmitted packet. If the ISITotalPeriod counter is zero then ping packets will not change its value from zero. Both the *ISITotalPeriod* and *ISILocalPeriod* counters are reloaded by the next local packet transmit request after the *ISITotalPeriod* counter has reached zero and this local packet has priority over pings.

The amount of guaranteed ISI bandwidth allocated to both local and ping packets is determined by the values of the ISITotalPeriod and ISILocalPeriod registers. Local packets will always be given priority when the ISILocalPeriod counter is non-zero. Ping packets will be given priority when the ISILocalPeriod counter is zero and the ISITotalPeriod counter is still non-zero.

Note that ping packets are very likely to get more than their guaranteed bandwidth as they will be transmitted whenever the ISI bus would otherwise be idle (i.e. no pending local packets). In particular when the ISITotalPeriod counter is zero it will not be reloaded until another local packet is pending and so ping packets transmitted when the ISITotalPeriod counter is zero will be in addition to the guaranteed bandwidth. Local packets on the other hand will never get more than their guaranteed bandwidth because each local packet transmitted decrements both counters and will cause the counters to be reloaded when the ISITotalPeriod counter is zero. The difference between the values of the ISITotalPeriod and ISILocalPeriod registers determines the number of automatically generated ping packets that are guaranteed to be transmitted every ISITotalPeriod number of ISI transactions. If the ISITotalPeriod and ISILocalPeriod values are the same then the

local packets will always get priority and could totally exclude ping packets if the CPU always has

For example if ISITotalPeriod = 0xC; ISILocalPeriod = 0x8; PingSchedule0 = 0x0E; PingSchedule1 = 0x0C and PingSchedule2 = 0x08 then four ping messages are guaranteed to be sent in every 12 ISI transactions. Furthermore ISIId3 will receive 3 times the number of ping packets as ISId1 and ISIId2 will receive twice as many as ISId1. Thus over a period of 36 contended ISI transactions (allowing for two full rotations through the three PingScheduleN registers) when local packets are always pending 24 local packets will be sent, ISId1 will receive 2 ping packets, ISId2 will receive 4 pings and ISId3 will receive 6 ping packets. If local traffic is less frequent then the ping frequency will automatically adjust upwards to consume all remaining ISI bandwidth.

12.4.5 Wake-up from Sleep Mode

5

10

15

30

35

40

packets to send.

Either the PrintMaster SoPEC or the external host may place any of the ISISlave SoPECs in sleep mode prior to going into sleep mode itself. The ISISlave device should then ensure that its <code>ISIWakeupEnable</code> bit of the <code>WakeupEnable</code> register (see Table 34) is set prior to entering sleep mode. In an ISISlave device the ISI block will continue to receive power and clock during sleep mode so that it may monitor the <code>gpio_isi_din</code> lines for activity. When ISI activity is detected during sleep mode and the <code>ISIWakeupEnable</code> bit is set the ISI asserts the <code>isi_cpr_reset_n</code> signal. This will bring the rest of the chip out of sleep mode by means of a wakeup reset. See chapter 16 for more details of reset propagation.

12.4.6 Implementation

Although the ISI consists of either 2 or 4 ISI data lines over which a serial data stream is demultiplexed, each ISI line is treated as a separate serial link at the physical layer. This permits a certain amount of skew between the ISI lines that could not be tolerated if the lines were treated as

a parallel bus. A lower Bit Error Rate (BER) can be achieved if the serial data recovery is performed separately on each serial link. Figure 39 illustrates the ISI sub block partitioning.

12.4.6.1 ISI Sub-block Partition

* Definition of I/Os.

Table 34. ISI I/O

5

Port name	Pins	1/0	Description
Clock and Reset			
isi_pclk	1	In	ISI primary clock.
isi_reset_n	1	In	ISI reset. Active low.
			Asserting isi_reset_n will reset all ISI logic.
			Synchronous to isi_pclk.
Configuration			
isi_go	1	In	ISI GO. Active high.
			When GO is de-asserted, all ISI statemachines are
			reset to their idle states, all ISI output signals are de-
			asserted, but all ISI counters retain their values.
			When GO is asserted, all ISI counters are reset and all
			ISI statemachines and output signals will return to their
			normal mode of operation.
isi_master_select	1	In	ISI master select.
			Determines whether the SoPEC is an ISIMaster or not
			1 = ISIMaster
			0 = ISISlave
isi_id[3:0]	4	In	ISI ID for this device.
isi_retries[3:0]	4	In	ISI number of retries.
			Number of times a transmitting ISI device will attempt
			retransmission of a NAK'd packet before aborting the
			transmission and flagging an error. The value of this
			configuration signal should not be changed while there
			are valid packets in the Tx buffer.
isi_ping_schedule0[1	15	In	ISI auto ping schedule #0.
4 :0]			Denotes which ISIIds will be receive ping packets. Note
-			that bit0 refers to ISIId0, bit1 to ISIId1bit14 to ISIId14.
			Setting a bit in this schedule will enable auto ping
			generation for the corresponding ISI ID. The ISI will
			start from the bit 0 of isi_ping_schedule0 and cycle
			through to bit 14, generating pings for each bit that is
			set. This operation will be performed in sequence from

			isi_ping_schedule0 through isi_ping_schedule2.
isi_ping_schedule1[1	15	In	As per isi_ping_schedule0.
4 :0]			
isi_ping_schedule2[1	15	in	As per isi_ping_schedule0.
4 :0]			no por ioriganigación da acorda
isi_total_period[3:0]	4	In	Reload value of the ISI Total Period Counter.
isi_local_period[3:0]	4	În	Reload value of the ISI Local Period Counter.
isi_number_pins	1	In	Number of active ISI data pins.
			Used to select how many serial data pins will be used
			to transmit and receive data. Should reflect the number
			of ISI device data pins that are in use.
			1 = isi_data[3:0] active
			0 = isi_data[1:0] active
isi_turn_around[3:0]	4	In	ISI bus turn around time in ISI clock cycles (32MHz).
isi_short_reply_win[4:	5	In	ISI long packet reply window in ISI clock cycles
0]			(32MHz).
isi_long_reply_win[8:	9	In	ISI long packet reply window in ISI clock cycles
0]			(32MHz).
isi_tx_enable	1	In	ISI transmit enable. Active high.
			Enables ISI transmission of long or ping packets. ACKs
:			may still be transmitted when this bit is 0. The value of
		į	this configuration signal should not be changed while
			there are valid packets in the Tx buffer.
isi_rx_enable	1	In	ISI receive enable. Active high.
			Enables ISI packet reception. Any activity on the ISI
			bus will be ignored when this signal is de-asserted.
•			This signal should only be de-asserted if the ISI block
			is not required for use in the design.
isi_bit_stuff_rate[3:0]	1	In	ISI bit stuffing limit.
			Allows the bit stuffing counter value to be programmed.
			Is loaded into the 4 upper bits of the 7bit wide bit
			stuffing counter. The lower bits are always loaded with
			b111, to prevent bit stuffing for less than 7 consecutive
			ones or zeroes. E.g.
			b000 : stuff_count = b0000111 : bit stuff after 7
			consecutive 0/1
			b111 : stuff_count = b11111111: bit stuff after127
			consecutive 0/1
Serial Link Signals	L	1	L
L			

isi_ser_data_in[3:0]	4	ln	ISI Serial data inputs.
	['''	Each bit corresponds to a separate serial link.
isi_ser_data_out[3:0]	4	Out	
ISI_Ser_data_but[5:0]	ľ	Out	ISI Serial data outputs.
	ļ	<u> </u>	Each bit corresponds to a separate serial link.
isi_ser_data_en[3:0]	4	Out	ISI Serial data driver enables. Active high.
	<u> </u>		Each bit corresponds to a separate serial link.
Tx Packet Buffer			
isi_tx_wr_en	1	In	ISI Tx FIFO write enable. Active high.
			Asserting <i>isi_tx_wr_en</i> will write the 64 bit data on
			isi_tx_wr_data to the FIFO, providing that space is
			available in the FIFO. If isi_tx_wr_en remains asserted
	1		after the last entry in the current packet is written, the
			write operation will wrap around to the start of the next
			packet, providing that space is available for a second
			packet in the FIFO.
isi_tx_wr_data[63:0]	64	ln	ISI Tx FIFO write data.
isi_tx_ping	1	ln ln	ISI Tx FIFO ping packet select. Active high.
, _			Asserting isi_tx_ping will queue a ping packet for
	<u> </u>		transmission, as opposed to a long packet. Although
			there is no data payload for a ping packet, a packet
			location in the FIFO is used as a 'place holder' for the
			ping packet. Any data written to the associated packet
			location in the FIFO will be discarded when the ping
·			packet is transmitted.
 isi_tx_id[3:0]	5		
SI_K_ U[3.0] 	5	ln	ISI Tx FIFO packet ID.
			ISI ID for each packet written to the FIFO. Registered
	ļ		when the last entry of the packet is written.
isi_tx_sub_id	1	ln	ISI Tx FIFO packet sub ID.
			ISI sub ID for each packet written to the FIFO.
			Registered when the last entry of the packet is written.
isi_tx_pkt_count[1:0]	2	Out	ISI Tx FIFO packet count.
			Indicates the number of packets contained in the FIFO.
			The FIFO has a capacity of 2 x 256 bit packets. Range
			is b00->b10.
isi_tx_word_count[2:0	3	Out	ISI Tx FIFO current packet word count.
þ			Indicates the number of words contained in the current
			Tx packet location of the Tx FIFO. Each packet location
			has a capacity of 4 x 64 bit words. Range is b000-
			>b100.
	!	1	

isi_tx_empty	1	Out	ISI Tx FIFO empty. Active high.
,			Indicates that no packets are present in the FIFO.
isi_tx_full	1	Out	ISI Tx FIFO full. Active high.
			Indicates that 2 packets are present in the FIFO,
			therefore no more packets can be transmitted.
isi_tx_over_flow	1	Out	ISI Tx FIFO over flow. Active high.
			Indicates that a write operation was performed on a full
			FIFO. The write operation will have no effect on the
			contents of the FIFO or the write pointer.
isi_tx_error	1	Out	ISI Tx FIFO error. Active high.
			Indicates that an error occurred while transmitting the
			packet currently at the head of the FIFO. This will
			happen if the number of transmission attempts exceeds
			isi_tx_retries.
isi_tx_desc[2:0]	3	Out	ISI Tx packet descriptor field.
			ISI packet descriptor field for the packet currently at the
			head of the FIFO. See Table for details. Only valid
			when isi_tx_empty=0, i.e. when there is a valid packet
			in the FIFO.
isi_tx_addr[4:0]	5	Out	ISI Tx packet address field.
			ISI address field for the packet currently at the head of
			the FIFO. See Table for details. Only valid when
			isi_tx_empty=0, i.e. when there is a valid packet in the
			FIFO.
Rx Packet FIFO	1	1	
isi_rx_rd_en	1	In	ISI Rx FIFO read enable. Active high.
	1		Asserting isi_rx_rd_en will drive isi_rx_rd_data with
			valid data, from the Rx packet at the head of the FIFO,
			providing that data is available in the FIFO. If
			isi_rx_rd_en remains asserted after the last entry is
			read from the current packet, the read operation will
			wrap around to the start of the next packet, providing
			that a second packet is available in the FIFO.
isi_rx_rd_data[63:0]	64	Out	ISI Rx FIFO read data.
isi_rx_sub_id	1	Out	ISI Rx packet sub ID.
			Indicates the ISI sub ID associated with the packet at
			the head of the Rx FIFO.
isi_rx_pkt_count[1:0]	2	Out	ISI Rx FIFO packet count.
			Indicates the number of packets contained in the FIFO.

			The FIFO has a capacity of 2 x 256 bit packets. Range
			is b00->b10.
isi_rx_word_count[2:0	3	Out	ISI Rx FIFO current packet word count.
þ			Indicates the number of words contained in the Rx
			packet location at the head of the FIFO. Each packet
			location has a capacity of 4 x 64 bit words. Range is
			b000->b100.
isi_rx_empty	1	Out	ISI Rx FIFO empty. Active high.
			Indicates that no packets are present in the FIFO.
isi_rx_full	1	Out	ISI Rx FIFO full. Active high.
			Indicates that 2 packets are present in the FIFO,
			therefore no more packets can be received.
isi_rx_over_flow	1	Out	ISI Rx FIFO over flow. Active high.
·			Indicates that a packet was addressed to the local ISI
			device, but the Rx FIFO was full, resulting in a NAK.
isi_rx_under_run	1	Out	ISI Rx FIFO under run. Active high.
			Indicates that a read operation was performed on an
			empty FIFO. The invalid read will return the contents of
			the memory location currently addressed by the FIFO
			read pointer and will have no effect on the read pointer.
isi_rx_frame_error	1	Out	ISI Rx framing error. Active high.
			Asserted by the ISI when a framing error is detected in
			the received packet, which can be caused by an
			incorrect Start or Stop field or by bit stuffing errors. The
			associated packet will be dropped.
isi_rx_crc_error	1 .	Out	ISI Rx CRC error. Active high.
			Asserted by the ISI when a CRC error is detected in an
			incoming packet. Other than dropping the errored
			packet ISI reception is unaffected by a CRC Error.

12.4.6.2 ISI Serial Interface Engine (isi_sie)

5

There are 4 instantiations of the *isi_sie* sub block in the ISI, 1 per ISI serial link. The *isi_sie* is responsible for Rx serial data sampling, Tx serial data output and bit stuffing.

Data is sampled based on a phase detection mechanism. The incoming ISI serial data stream is over sampled 5 times per ISI bit period. The phase of the incoming data is determined by detecting transitions in the ISI serial data stream, which indicates the ISI bit boundaries. An ISI bit boundary is defined as the sample phase at which a transition was detected.

The basic functional components of the isi_sie are detailed in Figure 40. These components are simply a grouping of logical functionality and do not necessarily represent hierarchy in the design.

10 12.4.6.2.1 SIE Edge Detection and Data I/O

The basic structure of the data I/O and edge detection mechanism is detailed in Figure 41.

NOTE: Serial data from the receiver in the pad MUST be synchronized to the *isi_pclk* domain with a 2 stage shift register external to the ISI, to reduce the risk of metastability. *ser_data_out* and *ser_data_en* should be registered externally to the ISI.

The Rx/Tx statemachine drives ser_data_en, stuff_1_en and stuff_0_en. The signals stuff_1_en and stuff_0_en cause a one or a zero to be driven on ser_data_out when they are asserted, otherwise fifo_rd_data is selected.

12.4.6.2.2 SIE Rx/Tx Statemachine

5

20

The Rx/Tx statemachine is responsible for the transmission of ISI Tx data and the sampling of ISI Rx data. Each ISI bit period is 5 *isi_pclk* cycles in duration.

- The Tx cycle of the Rx/Tx statemachine is illustrated in Figure 42. It generates each ISI bit that is transmitted. States tx0->tx4 represent each of the 5 *isi_pclk* phases that constitute a Tx ISI bit period. *ser_data_en* controls the tristate enable for the ISI line driver in the bidirectional pad, as shown in Figure 41. *rx_tx_cycle* is asserted during both Rx and Tx states to indicate an active Rx or Tx cycle. It is primarily used to enable bit stuffing.
- NOTE: All statemachine signals are assumed to be '0' unless otherwise stated.

The Tx cycle for Tx bit stuffing when the Rx/Tx statemachine inserts a '0' into the bitstream can be seen in Figure 43.

NOTE: All statemachine signals are assumed to be '0' unless otherwise stated

The Tx cycle for Tx bit stuffing when the RxTx statemachine inserts a '1' into the bitstream can be seen in Figure 44.

NOTE: All statemachine signals are assumed to be '0' unless otherwise stated
The tx^* and $stuff^*$ states are detailed separately for clarity. They could be easily combined when coding the statemachine, however it would be better for verification and debugging if they were kept separate.

The Rx cycle of the ISI Rx/Tx statemachine is detailed in Figure 45. The Rx cycle of the Rx/Tx Statemachine, samples each ISI bit that is received. States rx0->rx4 represent each of the 5 *isi_pclk* phases that constitute a Rx ISI bit period.

The optimum sample position for an ideal ISI bit period is 2 *isi_pclk* cycles after the ISI bit boundary sample, which should result in a data sample close to the centre of the ISI bit period.

rx_sample is asserted during the rx2 state to indicate a valid ISI data sample on rx_bit, unless the bit should be stripped when flagged by the bit stuffing statemachine, in which case rx_sample is not asserted during rx2 and the bit is not written to the FIFO. When edge is asserted, it resets the Rx cycle to the rx0 state, from any rx state. This is how the isi_sie tracks the phase of the incoming data. The Rx cycle will cycle through states rx0->rx4 until edge is asserted to reset the sample
 phase, or a tx_reg is asserted indicating that the ISI needs to transmit.

Due to the 5 times oversampling a maximum phase error of 0.4 of an ISI bit period (2 isi_pclk cycles

NOTE: All statemachine signals are assumed to be '0' unless otherwise stated.

out of 5) can be tolerated.

An example of the Tx data generation mechanism is detailed in Figure 46. *tx_req* and *fifo_wr_tx* are driven by the framer block.

An example of the Rx data sampling functional timing is detailed in Figure 47. The dashed lines on the *ser_data_in_ff* signal indicate where the Rx/Tx statemachine perceived the bit boundary to be, based on the phase of the last ISI bit boundary. It can be seen that data is sampled during the same phase as the previous bit was, in the absence of a transition.

5 12.4.6.2.3 SIE Rx/Tx FIFO

packet to discard any residual data.

hence a 7 x 1 bit FIFO.

10

15

20

25

35

The Rx/Tx FIFO is a 7 x 1 bit synchronous look-ahead FIFO that is shared for Tx and Rx operations. It is required to absorb any Rx/Tx latency caused by bit stripping/stuffing on a per ISI line basis, i.e. some ISI lines may require bit stripping/stuffing during an ISI bit period while the others may not, which would lead to a loss of synchronization between the data of the different ISI lines, if a FIFO were not present in each *isi_sie*.

The basic functional components of the FIFO are detailed in Figure 48. tx_ready is driven by the Rx/Tx statemachine and selects which signals control the read and write operations. tx_ready =1 during ISI transmission and selects the $fifo_*tx$ control and data signals. tx_ready =0 during ISI reception and selects the $fifo_*rx$ control and data signals. $fifo_reset$ is driven by the Rx/Tx statemachine. It is active high and resets the FIFO and associated logic before/after transmitting a

The size of the FIFO is based on the maximum bit stuffing frequency and the size of the shift register used to segment/re-assemble the multiple serial streams in the ISI framing logic. The maximum bit stuffing frequency is every 7 consecutive ones or zeroes. The shift register used is 32 bits wide. This implies that the maximum number of stuffed bits encountered in the time it takes to fill/empty the shift register if 4. This would suggest that 4 x 1 bit would be the minimum *ideal* size of the FIFO. However it is necessary to allow for different skew and phase error between the ISI lines,

The FIFO is controlled by the *isi_sie* during packet reception and is controlled by the *isi_frame* block during packet transmission. This is illustrated in Figure 49. The signal *tx_ready* selects which mode the FIFO control signals operate in. When *tx_ready*=0, i.e. Rx mode, the *isi_sie* control signals *rx_sample*, *fifo_rd_rx* and *ser_data_in_ff* are selected. When *tx_ready*=1, i.e. Tx mode, the *sie_frame* control signals *fifo_wr_tx*, *fifo_rd_tx* and *fifo_wr_data_tx* are selected.

12.4.6.3 Bit Stuffing

Programmable bit stuffing is implemented in the *isi_sie*. This is to allow the system to determine the amount of bit stuffing necessary for a specific ISI system devices. It is unlikely that bit stuffing would be required in a system using a 100ppm rated crystal. However, a programmable bit stuffing implementation is much more versatile and robust.

The bit stuffing logic consists of a counter and a statemachine that track the number of consecutive ones or zeroes that are transmitted or received and flags the Rx/Tx statemachine when the bit stuffing limit has been reached. The counter, $stuff_count$, is a 7 bit counter, which decrements when rx_sample is asserted on a Rx cycle or when $fifo_rd_tx$ is asserted on a Tx cycle. The upper 4 bits of $stuff_count$ are loaded with $isi_bit_stuff_rate$. The lower 3 bits of $stuff_count$ are always loaded with b111, i.e. for $isi_bit_stuff_rate = b000$, the counter would be loaded with b0000111. This is to

prevent bit stuffing for less than 7 consecutive ones or zeroes. This allows the bit stuffing limit to be set in the range 7->127 consecutive ones or zeroes.

NOTE: It is extremely important that a change in the bit stuffing rate, <code>isi_bit_stuff_rate</code>, is carefully co-ordinated between ISI devices in a system. It is obvious that ISI devices will not be able to

communicate reliably with each other with different bit stuffing settings. It is recommended that all ISI devices in a system default to the safest bit stuffing rate (*isi_bit_stuff_rate* = b000) at reset. The system can then co-ordinate the change to an optimum bit stuffing rate.

The ISI bit stuffing statemachine Tx cycle is shown in Figure 50. The counter is loaded when *stuff_count_load* is asserted.

NOTE: All statemachine signals are assumed to be '0' unless otherwise stated.

The ISI bit stuffing statemachine Rx cycle is shown in Figure 51. It should be noted that the statemachine enters the strip state when *stuff_count=0x2*. This is because the statemachine can only transition to *rx0* or *rx1* when *rx_sample* is asserted as it needs to be synchronized to changes in sampling phase introduced by the Rx/Tx statemachine. Therefore a one or a zero has already

been sampled by the time it enters rx0 or rx1. This is not the case for the Tx cycle, as it will always have a stable 5 isi_pclk cycles per bit period and relies purely on the data value when entering tx0 or tx1. The Tx cycle therefore enters stuff1 or stuff0 when $stuff_count=0x1$.

NOTE: All statemachine signals are assumed to be '0' unless otherwise stated.

12.4.6.4 ISI Framing and CRC sub-block (isi_frame)

20 12.4.6.4.1 CRC Generation/Checking

A Cyclic Redundancy Checksum (CRC) is calculated over all fields except the start and stop fields for each long or ping packet transmitted. The receiving ISI device will perform the same calculation on the received packet to verify the integrity of the packet. The procedure used in the CRC generation/checking is the same as the Frame Checking Sequence (FCS) procedure used in

25 HDLC, detailed in ITU-T Recommendation T30[39].

For generation/checking of the CRC field, the shift register illustrated in Figure 52 is used to perform the modulo 2 division on the packet contents by the polynomial $G(x) = x^{16} + x^{12} + x^5 + 1$.

To generate the CRC for a transmitted packet, where T(x) = [Packet Descriptor field, Address field, Data Payload field] (a ping packet will not contain a data payload field).

- Set the shift register to 0xFFFF.
 - Shift T(x) through the shift register, LSB first. This can occur in parallel with the packet transmission.
 - Once the each bit of T(x) has been shifted through the register, it will contain the remainder of the modulo 2 division T(x)/G(x).
- Perform a ones complement of the register contents, giving the CRC field which is transmitted MSB first, immediately following the last bit of *M(x)*To check the CRC for a received packet, where R(x) = [Packet Descriptor field, Address field,

Data Payload field, CRC field] (a ping packet will not contain a data payload field).

Set the shift register to 0xFFFF.

- Shift R(x) through the shift register, LSB first. This can occur in parallel with the packet reception.
- Once each bit of the packet has been shifted through the register, it will contain the remainder of the modulo 2 division R(x)/G(x).
- The remainder should equal b0001110100001111, for a packet without errors.

12.5 CTRL (CONTROL SUB-BLOCK)

12.5.1 Overview

5

10

25

30

35

The CTRL is responsible for high level control of the SCB sub-blocks and coordinating access between them. All control and status registers for the SCB are contained within the CTRL and are accessed via the CPU interface. The other major components of the CTRL are the SCB Map logic and the DMA Manager logic.

12.5.2 SCB Mapping

In order to support maximum flexibility when moving data through a multi-SoPEC system it is possible to map any USB endpoint onto either DMAChannel within any SoPEC in the system.

The SCB map, and indeed the SCB itself is based around the concept of an ISIId and an ISISubId.

Each SoPEC in the system has a unique ISIId and two ISISubIds, namely ISISubId0 and ISISubId1.

We use the convention that ISISubId0 corresponds to DMAChannel0 in each SoPEC and ISISubId1 corresponds to DMAChannel1. The naming convention for the ISIId is shown in Table 35 below and this would correspond to a multi-SoPEC system such as that shown in Figure 27. We use the term ISIId instead of SoPECId to avoid confusion with the unique ChipID used to create the SoPEC_id_key (see chapter 17 and [9] for more details).

Table 35. ISIId naming convention

ISIId	SoPEC to which it refers
0 - 14	Standard device ISIIds (0 is the power-on reset value)
15	Broadcast ISIId

The combined ISIId and ISISubId therefore allows the ISI to address DMAChannel0 or DMAChannel1 on any SoPEC device in the system. The ISI, DMA manager and SCB map hardware use the ISIId and ISISubId to handle the different data streams that are active in a multi-SoPEC system as does the software running on the CPU of each SoPEC. In this document we will identify DMAChannels as *ISIx.y* where *x* is the ISIId and *y* is the ISISubId. Thus ISI2.1 refers to DMAChannel1 of ISISlave2. Any data sent to a broadcast channel, i.e. ISI15.0 or ISI15.1, are received by every ISI device in the system including the ISIMaster (which may be an ISI-Bridge). The USB device controller and software stacks however have no understanding of the ISIId and ISISubId but the Silverbrook printer driver software running on the external host does make use of the ISIId and ISISubId. USB is simply used as a data transport - the mapping of USB device endpoints onto ISIId and SubId is communicated from the external host Silverbrook code to the SoPEC Silverbrook code through USB control (or possibly bulk data) messages i.e. the mapping

information is simply data payload as far as USB is concerned. The code running on SoPEC is responsible for parsing these messages and configuring the SCB accordingly.

The use of just two DMAChannels places some limitations on what can be achieved without software intervention. For every SoPEC in the system there are more potential sources of data than there are sinks. For example an ISISlave could receive both control and data messages from the ISIMaster SoPEC in addition to control and data from the external host, either specifically addressed to that particular ISISlave or over the broadcast ISI channel. However all ISISlaves only have two possible data sinks, i.e. DMAChannel0 and DMAChannel1. Another example is the ISIMaster in a multi-SoPEC system which may receive control messages from each SoPEC in addition to control and data information from the external host (e.g. over USB). In this case all of the control messages are in contention for access to DMAChannel0. We resolve these potential conflicts by adopting the following conventions:

- 1) Control messages may be interleaved in a memory buffer: The memory buffer that the DMAChannel0 points to should be regarded as a central pool of control messages. Every control message must contain fields that identify the size of the message, the source and the destination of the control message. Control messages may therefore be multiplexed over a DMAChannel which allows several control message sources to address the same DMAChannel. Furthermore, if SoPEC-type control messages contain source and destination fields it is possible for the external host to send control messages to individual SoPECs over the ISI15.0 broadcast channel.
- 2) Data messages should not be interleaved in a memory buffer: As data messages are typically part of a much larger block of data that is being transferred it is not possible to control their contents in the same manner as is possible with the control messages. Furthermore we do not want the CPU to have to perform reassembly of data blocks. Data messages from different sources cannot be interleaved over the same DMAChannel the SCB map must be reconfigured each time a different data source is given access to the DMAChannel.
 - 3) Every reconfiguration of the SCB map requires the exchange of control messages: SoPEC's SCB map reset state is shown in Table and any subsequent modifications to this map require the exchange of control messages between the SoPEC and the external host. As the external host is expected to control the movement of data in any SoPEC system it is anticipated that all changes to the SCB map will be performed in response to a request from the external host. While the SoPEC could autonomously reconfigure the SCB map (this is entirely up to the software running on the SoPEC) it should not do so without informing the external host in order to avoid data being misrouted.

An example of the above conventions in operation is worked through in section 12.5.2.3.

35 12.5.2.1 SCB map rules

5

10

15

30

40

The operation of the SCB map is described by these 2 rules:

Rule 1: A packet is routed to the DMA manager if it originates from the USB device core and has an ISIId that matches the local SoPEC ISIId.

Rule 2: A packet is routed to the ISI if it originates from the CPU or has an ISIId that does not match the local SoPEC ISIId.

If the CPU erroneously addresses a packet to the ISIId contained in the *ISIId* register (i.e. the ISIId of the local SoPEC) then that packet will be transmitted on the ISI rather than be sent to the DMA manager. While this will usually cause an error on the ISI there is one situation where it could be beneficial, namely for initial dialog in a 2 SoPEC system as both devices come out of reset with an ISIId of 0:

12.5.2.2 External host to ISIMaster SoPEC communication

5

10

15

20

25

30

Although the SCB map configuration is independent of ISIMaster status, the following discussion on SCB map configurations assumes the ISIMaster is a SoPEC device rather than an ISI bridge chip, and that only a single USB connection to the external host is present. The information should apply broadly to an ISI-Bridge but we focus here on an ISIMaster SoPEC for clarity.

As the ISIMaster SoPEC represents the printer device on the PC USB bus it is required by the USB specification to have a dedicated control endpoint, EP0. At boot time the ISIMaster SoPEC will also require a bulk data endpoint to facilitate the transfer of program code from the external host. The simplest SCB map configuration, i.e. for a single stand-alone SoPEC, is sufficient for external host to ISIMaster SoPEC communication and is shown in Table 36.

Table 36. Single SoPEC SCB map configuration

Source	Sink
EP0	ISI0.0
EP1	ISI0.1
EP2	nc
EP3	nc
EP4	nc .

In this configuration all USB control information exchanged between the external host and SoPEC over EP0 (which is the only bidirectional USB endpoint). SoPEC specific control information (printer status, DNC info etc.) is also exchanged over EP0.

All packets sent to the external host from SoPEC over EP0 must be written into the DMA mapped EP buffer by the CPU (LEON-PC dataflow in Figure 29). All packets sent from the external host to SoPEC are placed in DRAM by the DMA Manager, where they can be read by the CPU (PC-DIU dataflow in Figure 29). This asymmetry is because in a multi-SoPEC environment the CPU will need to examine all incoming control messages (i.e. messages that have arrived over DMAChannel0) to ascertain their source and destination (i.e. they could be from an ISISlave and destined for the external host) and so the additional overhead in having the CPU move the short control messages to the EP0 FIFO is relatively small. Furthermore we wish to avoid making the SCB more complicated than necessary, particularly when there is no significant performance gain to be had as the control traffic will be relatively low bandwidth.

The above mechanisms are appropriate for the types of communication outlined in sections 12.1.2.1.1 through 12.1.2.1.4

12.5.2.3 Broadcast communication

The SCB configuration for broadcast communication is also the default, post power-on reset, configuration for SoPEC and is shown in Table 37.

Table 37. Default SoPEC SCB map configuration

5

10

Source	Sink
EP0	ISI0.0
EP1	ISI0.1
EP2	ISI15.0
EP3	ISI15.1
EP4	ISI1.1

USB endpoints EP2 and EP3 are mapped onto ISISubID0 and ISISubId1 of ISIId15 (the broadcast ISIId channel). EP0 is used for control messages as before and EP1 is a bulk data endpoint for the ISIMaster SoPEC. Depending on what is convenient for the boot loader software, EP1 may or may not be used during the initial program download, but EP1 is highly likely to be used for compressed page or other program downloads later. For this reason it is part of the default configuration. In this setup the USB device configuration will take place, as it always must, by exchanging messages over the control channel (EP0).

- One possible boot mechanism is where the external host sends the bootloader1 program code to all SoPECs by broadcasting it over EP3. Each SoPEC in the system then authenticates and executes the bootloader1 program. The ISIMaster SoPEC then polls each ISISlave (over the ISIx.0 channel). Each ISISlave ascertains its ISIId by sampling the particular GPIO pins required by the bootloader1 and reporting its presence and status back to the ISIMaster. The ISIMaster then passes this information back to the external host over EP0. Thus both the external host and the ISIMaster have knowledge of the number of SoPECs, and their ISIIds, in the system. The external host may then reconfigure the SCB map to better optimise the SCB resources for the particular multi-SoPEC system. This could involve simplifying the default configuration to a single SoPEC system or remapping the broadcast channels onto DMAChannels in individual ISISlaves.
- The following steps are required to reconfigure the SCB map from the configuration depicted in Table to one where EP3 is mapped onto ISI1.0:
 - 1) The external host sends a control message(s) to the ISIMaster SoPEC requesting that USB EP3 be remapped to ISI1.0
- 12) The ISIMaster SoPEC sends a control message to the external host informing it that EP3 has
 30 now been mapped to ISI1.0 (and therefore the external host knows that the previous mapping of ISI15.1 is no longer available through EP3).
 - 3) The external host may now send control messages directly to ISISlave1 without requiring any CPU intervention on the ISIMaster SoPEC
 - 12.5.2.4 External host to ISISlave SoPEC communication

If the ISIMaster is configured correctly (e.g. when the ISIMaster is a SoPEC, and that SoPEC's SCB map is configured correctly) then data sent from the external host destined for an ISISlave will be transmitted on the ISI with the correct address. The ISI automatically forwards any data addressed to it (including broadcast data) to the DMA channel with the appropriate ISISubId. If the ISISlave has data to send to the external host it must do so by sending a control message to the ISIMaster identifying the external host as the intended recipient. It is then the ISIMaster's responsibility to forward this message to the external host.

With this configuration the external host can communicate with the ISISlave via broadcast messages only and this is the mechanism by which the bootloader1 program is downloaded. The ISISlave is unable to communicate with the external host (or the ISIMaster) until the bootloader1 program has successfully executed and the ISISlave has determined what its ISIId is. After the bootloader1 program (and possibly other programs) has executed the SCB map of the ISIMaster may be reconfigured to reflect the most appropriate topology for the particular multi-SoPEC system it is part of.

All communication from an ISISlave to external host is either achieved directly (if there is a direct USB connection present for example) or by sending messages via the ISIMaster. The ISISlave can never initiate communication to the external host. If an ISISlave wishes to send a message to the external host via the ISIMaster it must wait until it is pinged by the ISIMaster and then send a the message in a long packet addressed to the ISIMaster. When the ISIMaster receives the message from the ISISlave it first examines it to determine the intended destination and will then copy it into the EP0 FIFO for transmission to the external host. The software running on the ISIMaster is responsible for any arbitration between messages from different sources (including itself) that are all destined for the external host.

The above mechanisms are appropriate for the types of communication outlined in sections 12.1.2.1.5 and 12.1.2.1.6.

12.5.2.5 ISIMaster to ISISlave communication

5

10

25

30

35

40

All ISIMaster to ISISlave communication takes place over the ISI. Immediately after reset this can only be by means of broadcast messages. Once the bootloader1 program has successfully executed on all SoPECs in a multi-SoPEC system the ISIMaster can communicate with each SoPEC on an individual basis.

If an ISISlave wishes to send a message to the ISIMaster it may do so in response to a ping packet from the ISIMaster. When the ISIMaster receives the message from the ISISlave it must interpret the message to determine if the message contains information required to be sent to the external host. In the case of the ISIMaster being a SoPEC, software will transfer the appropriate information into the EPO FIFO for transmission to the external host.

The above mechanisms are appropriate for the types of communication outlined in sections 12.1.2.3.3 and 12.1.2.3.4.

12.5.2.6 ISISlave to ISISlave communication

ISISlave to ISISlave communication is expected to be limited to two special cases: (a) when the PrintMaster is not the ISIMaster and (b) when a storage SoPEC is used. When the PrintMaster is not the ISIMaster then it will need to send control messages (and receive responses to these messages) to other ISISlaves. When a storage SoPEC is present it may need to send data to each SoPEC in the system. All ISISlave to ISISlave communication will take place in response to ping messages from the ISIMaster.

After reset any SoPEC (regardless of ISIMaster/Slave status) with an active USB connection will route packets from EP0,1 to DMA channels 0,1 because the default SCB map is to map EP0 to ISIId0.0 and EP1 to ISIId0.1 and the default ISIId is 0. At some later time the SoPEC learns its true ISIId for the system it is in and re-configures its ISIId and SCB map registers accordingly. Thus if the true ISIId is 3 the external host could reconfigure the SCB map so that EP0 and EP1 (or any other endpoints for that matter) map to ISIId3.0 and 3.1 respectively. The co-ordination of the updating of the ISIId registers and the SCB map is a matter for software to take care of. While the *AutoMasterEnable* bit of the *ISICntrl* register is set the external host must not send packets down EP2-4 of the USB connection to the device intended to be an ISISlave. When *AutoMasterEnable* has been cleared the external host may send data down any endpoint of the USB connection to the ISISlave.

The SCB map of an ISISlave can be configured to route packets from any EP to any ISIId.ISISubId (just as an ISIMaster can). As with an ISIMaster these packets will end up in the SCBTxBuffer but while an ISIMaster would just transmit them when it got a local access slot (from ping arbitration) the ISISlave can only transmit them in response to a ping. All this would happen without CPU intervention on the ISISlave (or ISIMaster) and as long as the ping frequency is sufficiently high it would enable maximum use of the bandwidth on both USB buses.

12.5.3 DMA Manager

5

10

15

20

25

30

35

The DMA manager manages the flow of data between the SCB and the embedded DRAM. Whilst the CPU could be used for the movement of data in SoPEC, a DMA manager is a more efficient solution as it will handle data in a more predictable fashion with less latency and requiring less buffering. Furthermore a DMA manager is required to support the ISI transfer speed and to ensure that the SoPEC could be used with a high speed ISI-Bridge chip in the future.

The DMA manager utilizes 2 write channels (DMAChannel0, DMAChannel1) and 1 read/write channel (DMAChannel2) to provide 2 independent modes of access to DRAM via the DIU interface:

- USBD/ISI type access.
- USBH type access.

DIU read and write access is in bursts of 4x64 bit words. Byte aligned write enables are provided for write access. Data for DIU write accesses will be read directly from the buffers contained in the respective SCB sub-blocks. There is no internal SCB DMA buffer. The DMA manager handles all issues relating to byte/ word/longword address alignment, data endianness and transaction scheduling. If a DMA channel is disabled during a DMA access, the access will be completed. Arbitration will be performed between the following DIU access requests:

- USBD write request.
- 40 ISI write request.

- USBH write request.
- USBH read request.

5

20

30

35

40

DMAChannel0 will have absolute priority over any DMA requestors. In the absence of DMAChannel0 DMA requests, arbitration will be performed in a round robin manner, on a per cycle basis over the other channels.

12.5.3.1 DMA Effective Bandwidth

The DIU bandwidth available to the DMA manager must be set to ensure adequate bandwidth for all data sources, to avoid back pressure on the USB and the ISI. This is achieved by setting the output (i.e. DIU) bandwidth to be greater than the combined input bandwidths (i.e. USBD + USBH + ISI).

The required bandwidth is expected to be 160 Mbits/s (1 bit/cycle @ 160MHz). The guaranteed DIU bandwidth for the SCB is programmable and may need further analysis once there is better knowledge of the data throughput from the USB IP cores.

12.5.3.2 USBD/ISI DMA access

The DMA manager uses the two independent unidirectional write channels for this type of DMA access, one for each ISISubId, to control the movement of data. Both DMAChannel0 and DMAChannel1 only support write operation and can transfer data from any USB device DMA mapped EP buffer and from the ISI receive buffer to separate circular buffers in DRAM, corresponding to each DMA channel.

While the DMA manager performs the work of moving data the CPU controls the destination and relative timing of data flows to and from the DRAM. The management of the DRAM data buffers requires the CPU to have accurate and timely visibility of both the DMA and PEP memory usage. In other words when the PEP has completed processing of a page band the CPU needs to be aware of the fact that an area of memory has been freed up to receive incoming data. The management of these buffers may also be performed by the external host.

25 12.5.3.2.1 Circular buffer operation

The DMA manager supports the use of circular buffers for both DMAChannels. Each circular buffer is controlled by 5 registers: *DMAnBottomAdr, DMAnTopAdr, DMAnMaxAdr, DMAnCurrWPtr* and *DMAnIntAdr.* The operation of the circular buffers is shown in Figure 53 below.

Here we see two snapshots of the status of a circular buffer with (b) occurring sometime after (a) and some CPU writes to the registers occurring in between (a) and (b). These CPU writes are most likely to be as a result of a finished band interrupt (which frees up buffer space) but could also have occurred in a DMA interrupt service routine resulting from *DMAnIntAdr* being hit. The DMA manager will continue filling the free buffer space depicted in (a), advancing the *DMAnCurrWPtr* after each write to the DIU. Note that the *DMACurrWPtr* register always points to the next address the DMA manager will write to. When the DMA manager reaches the address in *DMAnIntAdr* (i.e.

DMACurrWPtr = DMAnIntAdr) it will generate an interrupt if the DMAnIntAdrMask bit in the DMAMask register is set. The purpose of the DMAnIntAdr register is to alert the CPU that data (such as a control message or a page or band header) has arrived that it needs to process. The interrupt routine servicing the DMA interrupt will change the DMAnIntAdr value to the next location that data of interest to the CPU will have arrived by.

In the scenario shown in Figure 53 the CPU has determined (most likely as a result of a finished band interrupt) that the filled buffer space in (a) has been freed up and is therefore available to receive more data. The CPU therefore moves the *DMAnMaxAdr* to the end of the section that has been freed up and moves the *DMAnIntAdr* address to an appropriate offset from the *DMAnMaxAdr* address. The DMA manager continues to fill the free buffer space and when it reaches the address in *DMAnTopAdr* it wraps around to the address in *DMAnBottomAdr* and continues from there. DMA transfers will continue indefinitely in this fashion until the DMA manager reaches the address in the *DMAnMaxAdr* register.

The circular buffer is initialized by writing the top and bottom addresses to the *DMAnTopAdr* and *DMAnBottomAdr* registers, writing the start address (which does not have to be the same as the *DMAnBottomAdr* even though it usually will be) to the *DMAnCurrWPtr* register and appropriate addresses to the *DMAnIntAdr* and *DMAnMaxAdr* registers. The DMA operation will not commence until a 1 has been written to the relevant bit of the *DMAChanEn* register.

While it is possible to modify the *DMAnTopAdr* and *DMAnBottomAdr* registers after the DMA has started it should be done with caution. The *DMAnCurrWPtr* register should not be written to while the DMAChannel is in operation. DMA operation may be stalled at any time by clearing the appropriate bit of the *DMAChanEn* register or by disabling an SCB mapping or ISI receive operation.

12.5.3.2.2 Non-standard buffer operation

5

15

30

35

40

- The DMA manager was designed primarily for use with a circular buffer. However because the DMA pointers are tested for equality (i.e. interrupts generated when DMAnCurrWPtr = DMAIntAdr or DMAnCurrWPtr = DMAMaxAdr) and no bounds checking is performed on their values (i.e. neither DMAnIntAdr nor DMAnMaxAdr are checked to see if they lie between DMAnBottomAdr and DMAnTopAdr) a number of non-standard buffer arrangements are possible. These include:
- Dustbin buffer: If DMAnBottomAdr, DMAnTopAdr and DMAnCurrWPtr all point to the same location and both DMAnIntAdr and DMAnMaxAdr point to anywhere else then all data for that DMA channel will be dumped into the same location without ever generating an interrupt.

 This is the equivalent to writing to /dev/null on Unix systems.
 - Linear buffer: If DMAnMaxAdr and DMAnTopAdr have the same value then the DMA
 manager will simply fill from DMAnBottomAdr to DMAnTopAdr and then stop. DMAnIntAdr
 should be outside this buffer or have its interrupt disabled.

12.5.3.3 USBH DMA access

The USBH requires DMA access to DRAM in to provide a communication channel between the USB HC and the USB HCD via a shared memory resource. The DMA manager uses two independent channels for this type of DMA access, one for reads and one for writes. The DRAM addresses provided to the DIU interface are generated based on addresses defined in the USB HC core operational registers, in USBH section 12.3.

12.5.3.4 Cache coherency

As the CPU will be processing some of the data transferred (particularly control messages and page/band headers) into DRAM by the DMA manager, care needs to be taken to ensure that the

data it uses is the most recently transferred data. Because the DMA manager will be updating the circular buffers in DRAM without the knowledge of the cache controller logic in the LEON CPU core the contents of the cache can become outdated. This situation can be easily handled by software, for example by flushing the relevant cache lines, and so there is no hardware support to enforce cache coherency.

12.5.4 ISI transmit buffer arbitration

The SCB control logic will arbitrate access to the ISI transmit buffer (ISITxBuffer) interface on the ISI block. There are two sources of ISI Tx packets:

- CPUISITxBuffer, contained in the SCB control block.
- ISI mapped USB EP OUT buffers, contained in the USB device block.

This arbitration is controlled by the *ISITxBuffArb* register which contains a high priority bit for both the CPU and the USB. If only one of these bits is set then the corresponding source always has priority. Note that if the CPU is given absolute priority over the USB, then the software filling the ISI transmit buffer needs to ensure that sufficient USB traffic is allowed through. If both bits of the

15 ISITxBufferArb have the same value then arbitration will take place on a round robin basis.

The control logic will use the *USBEPnDest registers*, as it will use the *CPUISITxBuffCntrl* register, to determine the destination of the packets in these buffers. When the ISITxBuffer has space for a packet, the SCB control logic will immediately seek to refill it. Data will be transferred directly from the CPUISITxBuffer and the ISI mapped USB EP OUT buffers to the ISITxBuffer without any

20 intermediate buffering.

5

As the speed at which the ISITxBuffer can be emptied is at least 5 times greater than it can be filled by USB traffic, the ISI mapped USB EP OUT buffers should not overflow using the above scheme in normal operation. There are a number of scenarios which could lead to the USB EPs being temporarily blocked such as the CPU having priority, retransmissions on the ISI bus, channels being enabled (*ChannelEn* bit of the *USBEPnDest* register) with data already in their associated endpoint buffers or short packets being sent on the USB. Care should be taken to ensure that the USB bandwidth is efficiently utilised at all times.

12.5.5 Implementation

12.5.5.1 CTRL Sub-block Partition

30 * Block Diagram

25

35

* Definition of I/Os

12.5.5.2 SCB Configuration Registers

The SCB register map is listed in Table 38. Registers are grouped according to which SCB subblock their functionality is associated. All configuration registers reside in the CTRL sub-block. The Reset values in the table indicates the 32 bit hex value that will be returned when the CPU reads the associated address location after reset. All Registers pre-fixed with *Hc* refer to Host Controller Operational Registers, as defined in the OHCI Spec[19].

The SCB will only allow supervisor mode accesses to data space (i.e. $cpu_acode[1:0] = b11$). All other accesses will result in scb_cpu_berr being asserted.

TDB: Is read access necessary for ISI Rx/Tx buffers? Could implement the ISI interface as simple FIFOs as opposed to a memory interface.

Table 38. SCB control block configuration registers

Addre ss Offse from SCB_ base		#Bits	Reset	Description
CTRL		1		
0×000	SCBResetN	4	0x000000F	SCB software reset.
				Allows individual sub-blocks to be reset
				separately or together. Once a reset for
				a block has been initiated, by writing a
				0 to the relevant register field, it can not
				be suppressed. Each field will be set
				after reset. Writing 0x0 to the
				SCBReset register will have the same
				effect as CPR generated hardware
				reset.
0x004	SCBGo	2	0x00000000	SCB Go.
·				Allows the ISI and CTRL sub-blocks to
				be selected separately or together.
				When go is de-asserted for a particular
				sub-block, its statemachines are reset
				to their idle states and its interface
				signals are de-asserted. The sub-block
				counters and configuration registers
				retain their values.
				When go is asserted for a particular
		ŀ		sub-block, its counters are reset. The
				sub-block configuration registers retain
				their values, i.e. they don't get reset.
				The sub-block statemachines and
:				interface signals will return to their
				normal mode of operation.
		ĺ		The CTRL field should be de-asserted
		-		before disabling the clock from any part
				of the SCB to avoid erroneous SCB
				DMA requests when the clock is
				enabled again.
				NOTE: This functionality has not been
				provided for the USBH and USBD sub-

				blocks because of the USB IP cores
				that they contain. We do not have
				direct control over the IP core
				statemachines and counters, and it
				would cause unpredictable behaviour if
				the cores were disabled in this way
				during operation.

0x3CC	ISIDebug	4	0x00000000	ISI debug register.
	<u> </u>			

A detailed description of each register format follows. The CPU has full read access to all registers. Write access to the fields of each register is defined as:

• Full: The CPU has full write access to the field, i.e. the CPU can write a 1 or a 0 to each bit.

- Clear: The CPU can clear the field by writing a 1 to each bit. Writing a 0 to this type of field will have no effect.
- None: The CPU has no write access to the field, i.e. a CPU write will have no effect on the field.

10 12.5.5.2.1 SCBResetN

Table 39. SCBResetN register format

Field Name	Bit(s)	write access	Description
CTRL	0	Full	scb_ctrl sub-block reset.
			Setting this field will reset the SCB control sub-block logic,
			including all configuration registers.
			0 = reset
			1 = default state
ISI	1	Full	scb_isi sub-block reset.
			Setting this field will reset the ISI sub-block logic.
			0 = reset
			1 = default state
USBH	2	Full	scb_usbh sub-block reset.
			Setting this field will reset the USB host controller core
			and associated logic.
			0 = reset
			1 = default state
USBD	3	Full	scb_usbd sub-block reset.
			Setting this field will reset the USB device controller core
			and associated logic.
			0 = reset
			1 = default state

12.5.5.2.2 SCBGo

Table 40. SCBGo register format

Field Name	Bit(s)	write access	Description
CTRL	0	Full	scb_ctrl sub-block go.
			0 = halted
		-	1 = running
ISI	1	Full	scb_isi sub-block go.
			0 = halted
			1 = running

12.5.5.2.3 SCBWakeUpEn

This register is used to gate the propagation of the USB and ISI reset signals to the CPR block.

Table 41. SCBWakeUpEn register format

Field Name	Bit(s)	write access	Description
USBWakeUpEn	0	Full	<i>usb_cpr_reset_n</i> propagation enable.
			1 = enable
			0 = disable
ISIWakeUpEn	1	Full	<i>isi_cpr_reset_n</i> propagation enable.

12.5.5.2.4 SCBISITxBufferArb

This register determines which source has priority at the ISITxBuffer interface on the ISI block. When a bit is set priority is given to the relevant source. When both bits have the same value, arbitration will be performed in a round-robin manner.

Table 42. SCBISITxBufferArb register format

Field Name	Bit(s)	write access	Description
CPUPriority	o	Full	CPU priority 1 = high priority 0 = low priority
USBPriority	1	Full	USB priority 1 = high priority 0 = low priority

12.5.5.2.5 SCBDebugSel

Contains address of the register selected for debug observation as it would appear on cpu_adr. The contents of the selected register are output in the scb_cpu_data bus while cpu_scb_sel is low and scb_cpu_debug_valid is asserted to indicate the debug data is valid. It is expected that a number of pseudo-registers will be made available for debug observation and these will be outlined with the implementation details.

Table 43. SCBDebugSel register format

15

25

10

5

CPLIAdr	11.2	access	cou, adr. register address
CPUAdr	11:2	Full	cpu_adr register address.

12.5.5.2.6 **USBEPnDest**

This register description applies to USBEP0Dest, USBEP1Dest, USBEP2Dest, USBEP3Dest, USBEP4Dest. The SCB has two routing options for each packet received, based on the DestISIId associated with the packets source EP:

- 20 To the DMA Manager
 - To the ISI

The SCB map therefore does not need special fields to identify the DMAChannels on the ISIMaster SoPEC as this is taken care of by the SCB hardware. Thus the USBEP0Dest and USBEP1Dest registers should be programmed with 0x20 and 0x21 (for ISI0.0 and ISI0.1) respectively to ensure data arriving on these endpoints is moved directly to DRAM.

Table 44. USBEPnDest register format

Field Name	Bit(s)	Write access	Description
SequenceBit	0	Full	Sequence bit for packets going from
			USBEPn to DestISIId.DestISISubId.
			Every CPU write to this register
			initialises the value of the sequence
			bit and this is subsequently updated
			by the ISI after every successful long
			packet transmission.
DestISIId	4:1	Full	Destination ISI ID.
			Denotes the ISIId of the target
			SoPEC as per Table
DestISISubId	5	Full	Destination ISI sub ID.
			Indicates which DMAChannel of the
			target SoPEC the endpoint is
			mapped onto:
			0 = DMAChannel0
			1 = DMAChannel1
ChannelEn	6	Full	Communication channel enable bit
			for EPn.
			This enables/disables the
			communication channel for EPn.
			When disabled, the SCB will not
			accept USB packets addressed to
			EPn.
			0 = Channel disabled
			1 = Channel enabled

If the local SoPEC is connected to an external USB host, it is recommended that the EP0 communication channel should always remain enabled and mapped to DMAChannel0 on the local SoPEC, as this is intended as the primary control communication channel between the external USB host and the local SoPEC.

A SoPEC ISIMaster should map as many USB endpoints, under the control of the external host, as are required for the multi-SoPEC system it is part of. As already mentioned this mapping may be dynamically reconfigured.

12.5.5.2.7 DMAnBottomAdr

5

10 This register description applies to *DMA0BottomAdr* and *DMA1BottomAdr*.

Table 45. DMAnBottomAdr register format

Field Name Bit(s) Write Description

AT SECULO		access	
DMAnBottomAdr	21:5		The 256-bit aligned DRAM address of the bottom of the circular buffer (inclusive)
			serviced by DMAChanneln

12.5.5.2.8 DMAnTopAdr

This register description applies to DMA0TopAdr and DMA1TopAdr.

Table 46. DMAnTopAdr register format

5

Field Name	``'		Description
DMAnTopAdr	21:5	access Full	The 256-bit aligned DRAM address of
			the top of the circular buffer (inclusive) serviced by DMAChanneln

12.5.5.2.9 DMAnCurrWPtr

This register description applies to DMA0CurrWPtr and DMA1CurrWPtr.

Table 47. DMAnCurrWptr register format

Field Name	Bit(s)	Write access	Description
DMAnCurrWPtr	21:5	Full	The 256-bit aligned DRAM address of the next location DMAChannel0 will write to. This register is set by the CPU at the start of a DMA operation and dynamically updated by the DMA manager during the operation.

10 12.5.5.2.10 DMAnIntAdr

This register description applies to DMA0IntAdr and DMA1IntAdr.

Table 48. DMAnIntAdr register format

		Write access	Description
DMAnIntAdr	21:5		The 256-bit aligned DRAM address of the location that will trigger an interrupt when reached by DMAChanneln buffer.

12.5.5.2.11

DMAnMaxAdr

15 This register description applies to *DMA0MaxAdr* and *DMA1MaxAdr*.

Table 49. DMAnMaxAdr register format

Field Name	` '	Write access	Description
DMAnMaxAdr	21:5		The 256-bit aligned DRAM address of the last free location that in the DMAChanneln circular buffer. DMAChannel0 transfers will stop when it reaches this address.

12.5.5.2.12 DMAAccessEn

This register enables DMA access for the various requestors, on a per channel basis.

Table 50. DMAAccessEn register format

Field Name	Bit(s)	Write access	Description
DMAChannel0En	О	Full	DMA Channel #0 access enable. This uni-directional write channel is used by the USBD and the ISI. 1 = enable 0 = disable
DMAChannel1En	1	Full	As per <i>USBDISI0En</i> :
DMAChannel2En	2	Full	DMA Channel #2 access enable. This bi-directional read/write channel is used by the USBH. 1 = enable 0 = disable

5 12.5.5.2.13 DMAStatus

The status bits are not sticky bits i.e. they reflect the 'live' status of the channel.

DMAChannelNIntAdrHit and DMAChannelNMaxAdrHit status bits may only be cleared by writing to the relevant DMAnIntAdr or DMAnMaxAdr register.

Table 51. DMAStatus register format

Field Name	Bit(s)	Write access	Description
DMAChannel0IntAdrHit	О	None	DMA channel #0 interrupt address hit. 1= DMAChannel0 has reached the address contained in the <i>DMA0IntAdr</i> register. 0 = default state
DMAChannel0MaxAdrHit	1	None	DMA channel #0 max address hit. 1 = DMAChannel0 has reached the address contained in the DMA0MaxAdr

			register.
			0 = default state
DMAChannel1IntAdrHit	3	None	As per DMAChannel0IntAdrHit.
DMAChannel1MaxAdrHit	4	None	As per DMAChannel0MaxAdrHit.

12.5.5.2.14 DMAMask register

All bits of the *DMAMask* are both readable and writable by the CPU. The DMA manager cannot alter the value of this register. All interrupts are generated in an edge sensitive manner i.e. the DMA manager will generate a *dma_icu_irq* pulse each time a status bit goes high and its corresponding mask bit is enabled.

Table 52. DMAMask register format

Field Name	``'	Write access	Description
DMAChannel0IntAdrHitIntEn	0	Full	DMAChannel0IntAdrHit status interrupt
•			enable.
			1 = enable
			0 = disable
DMAChannel0MaxAdrHitIntEn	1	Full	DMAChannel0MaxAdrHit status interrupt
			enable.
			1 = enable
	ļ		0 = disable
DMAChannel1IntAdrHitIntEn	2	Full	As per DMAChannel0IntAdrHitIntEn
DMAChannel1MaxAdrHitIntEn	3	Full	As per DMAChannel0MaxAdrHitIntEn

12.5.5.2.15 CPUISITxBuffCtrl register

Table 53. CPUISITxBuffCtrl register format

10

Field Name	Bit(s)	Write access	Description
PktValid	O	full	This field should be set by the CPU to indicate the validity of the CPUISITxBuff contents. This field will be cleared by the SCB once the contents of the CPUISITxBuff has been copied to the ISITxBuff. NOTE: The CPU should not clear this field under normal operation. If the CPU clears this field during a packet
			transfer to the <i>ISITxBuff</i> , the transfer will be aborted - this is not

			recommended. 1 = valid packet. 0 = default state.
PktDesc	3:1	full	PktDesc field, as per Table , of the packet contained in the CPUISITxBuff. The CPU is responsible for maintaining the correct sequence bit value for each ISIId.ISISubId channel it communicates with. Only valid when CPU-ISITxBuffCtrl.PktValid = 1.
DestiSild	7:4	full	Denotes the <i>ISIId</i> of the target SoPEC as per Table .
DestISISubId	8	full	Indicates which DMAChannel of the target SoPEC the packet in the CPUISITxBuff is destined for. 1 = DMAChannel1 0 = DMAChannel0

12.5.5.2.16 USBDIntStatus

5

The *USBDIntStatus* register contains status bits that are related to conditions that can cause an interrupt to the CPU, if the corresponding interrupt enable bits are set in the *USBDMask* register.

The field name extension *Sticky* implies that the status condition will remain registered until cleared by a CPU write of 1 to each bit of the field.

NOTE: There is no *Ep0IrregPktSticky* field because the default control EP will frequently receive packets that are not multiples of 32 bytes during normal operation.

Table 54. USBDIntStatus register format

Field Name	Bit(s)	Write access	Description
CoreSuspendSticky	0	Clear	Device core USB suspend flag. Sticky. 1 = USB suspend state. Set when device core udcvci_suspend signal transitions from 1 -> 0. 0 = default value.
CoreUSBResetSticky	1	Clear	Device core USB reset flag. Sticky. 1 = USB reset. Set when device core udcvci_reset signal transitions from 1 -> 0. 0 = default value.
CoreUSBSOFSticky	2	Clear	Device core USB Start Of Frame (SOF) flag. Sticky. 1 = USB SOF. Set when device core

	T	Γ	udcvci_sof signal transitions from 1 -> 0
			0 = default value.
CPUISITxBuffEmptySticky	3	Clear	CPU ISI transmit buffer empty flag. Sticky.
			1 = empty.
			0 = default value.
CPUEp0InBuffEmptySticky	4	Clear	CPU EP0 IN buffer empty flag. Sticky.
			1 = empty.
			0 = default value.
CPUEp5InBuffEmptySticky	5	Clear	CPU EP5 IN buffer empty flag. Sticky.
	[1 = empty.
			0 = default value.
Ep0InNAKSticky	6	clear	EP0-IN NAK flag. Sticky
]			This flag is set if the USB device core issues
			a read request for EP0-IN and there is not a
			valid packet present in the EP0-IN buffer. The
			core will therefore send a NAK response to
			the IN token that was received from external
			USB host. This is an indicator of any back-
·			pressure on the USB caused by EP0-IN.
			1 = NAK sent.
			0 = default value
Ep5InNAKSticky	7	Clear	As per <i>Ep0InNAK</i> .
Ep0OutNAKSticky	8	Clear	EP0-OUT NAK flag. Sticky
			This flag is set if the USB device core issues
			a write request for EP0-OUT and there is no
			space in the OUT EP buffer for a the packet.
			The core will therefore send a NAK response
			to the OUT token that was received from
			external USB host. This is an indicator of any
			back-pressure on the USB caused by EP0-
			оит.
			1 = NAK sent.
			0 = default value
Ep1OutNAKSticky	9	Clear	As per <i>Ep0OutNAK</i> .
Ep2OutNAKSticky	10	Clear	As per <i>Ep0OutNAK</i> .
Ep3OutNAKSticky	11	Clear	As per Ep0OutNAK.
Ep4OutNAKSticky	12	Clear	As per Ep0OutNAK.
Ep1lrregPktSticky	13	Clear	EP1-OUT irregular sized packet flag. Sticky.
			Indicates a packet that is not a multiple of 32
		<u></u>	

			bytes in size was received by EP1-OUT. 1 = irregular sized packet received.
Ep2IrregPktSticky	14	Clear	0 = default value. As per <i>Ep1IrregPktSticky</i> .
Ep3IrregPktSticky	15	Clear	As per Ep1IrregPktSticky.
Ep4IrregPktSticky	16	Clear	As per Ep1IrregPktSticky.
OutBuffOverFlowSticky	17	Clear	OUT EP buffer overflow flag. Sticky. This flag is set if the USB device core attempted to write a packet of more than 64 bytes to the OUT EP buffer. This is a fatal error, suggesting a problem in the USB device IP core. The SCB will take no further action. 1 = overflow condition detected. 0 = default value.
InBuffUnderRunSticky	18	clear	IN EP buffer underrun flag. Sticky. This flag is set if the USB device core attempted to read more data than was present from the IN EP buffer. This is a fatal error, suggesting a problem in the USB device IP core. The SCB will take no further action. 1 = underrun condition detected. 0 = default value.

12.5.5.2.17 USBDISIFIFOStatus

This register contains the status of the ISI mapped OUT EP packet FIFO. This is a secondary status register and will not cause any interrupts to the CPU.

Table 55. USBDISIFIFOStatus register format

Field Name	Bit(s)	Write access	Description
Entry0Valid	0	none	FIFO entry #0 valid field.
]	This flag will be set by the USBD when the USB device core
]	indicates the validity of packet entry #0 in the FIFO.
			1 = valid USB packet in ISI OUT EP buffer 0.
			0 = default value.
Entry0Source	3:1	none	FIFO entry #0 source field.
			Contains the EP associated with packet entry #0 in the FIFO.
			Binary Coded Decimal.
			Only valid when ISIBuff0PktValid = 1.
Entry1Valid	4	none	As per <i>Entry0Valid</i> .

Entry1Source	7:5	none	As per Entry0Source.
Entry2Valid	8	none	As per <i>Entry0Valid</i> .
Entry2Source	11:9	none	As per Entry0Source.
Entry3Valid	12	none	As per Entry0Valid.
Entry3Source	15:13	none	As per Entry0Source.

12.5.5.2.18 USBDDMA0FIFOStatus

This register description applies to USBDDMA0FIFOStatus and USBDDMA1FIFOStatus.

This register contains the status of the DMAChannelN mapped OUT EP packet FIFO. This is a secondary status register and will not cause any interrupts to the CPU.

Table 56. USBDDMANFIFOStatus register format

Field Name	Bit(s)	Write access	Description
Entry0Valid	O	none	FIFO entry #0 valid field. This flag will be set by the USBD when the USB device core indicates the validity of packet entry #0 in the FIFO. 1 = valid USB packet in ISI OUT EP buffer 0. 0 = default value.
Entry0Source	3:1	none	FIFO entry #0 source field. Contains the EP associated with packet entry #0 in the FIFO. Binary Coded Decimal. Only valid when Entry0Valid = 1.
Entry1Valid	4	none	As per <i>Entry</i> 0Valid.
Entry1Source	7:5	none	As per Entry0Source.

^{12.5.5.2.19} USBDResume

This register causes the USB device core to initiate *resume* signalling to the external USB host.

Only applicable when the device core is in the suspend state.

10 Table 57. USBDResume register format

Field Name	Bit(s)	Write access	Description
USBDResume	0	full	USBD core resume register.
			The USBD will clear this register upon resume
			notification from the device core.
			1 = generate resume signalling.
			0 = default value.

12.5.5.2.20 USBDSetup

This register controls the general setup/configuration of the USBD.

Table 58. USBDSetup register format

Field Name	``'	write access	Description
Ep1IrregPktCntrl	0	full	EP 1 OUT irregular sized packet control.
			An irregular sized packet is defined as a packet that is not a
			multiple of 32 bytes.
			1 = discard irregular sized packets.
			0 = read 32 bytes from buffer, regardless of packet size.
Ep2IrregPktCntrl	1	full	As per Ep1IrregPktDiscard
Ep3IrregPktCntrl	2	full	As per Ep1lrregPktDiscard
Ep4lrregPktCntrl	3	full	As per Ep1lrregPktDiscard

12.5.5.2.21 USBDEpNInBuffCtrl register

This register description applies to USBDEp0InBuffCtrl and USBDEp5InBuffCtrl.

Table 59. USBDEpNInBuffCtrl register format

Field Name Bit(s) Write access	Description
PktValid 0 full	Setting this register validates the contents of USBDEpNInBuff. This field will be cleared by the SCB once the packet has been successfully transmitted to the external USB host. NOTE: The CPU should not clear this field under normal operation. If the CPU clears this field during a packet transfer to the USB, the transfer will be aborted - this is not recommended. 1 = valid packet. 0 = default state.

5 12.5.5.2.22 USBDMask

This register serves as an interrupt mask for all USBD status conditions that can cause a CPU interrupt. Setting a field enables interrupt generation for the associated status event. Clearing a field disables interrupt generation for the associated status event. All interrupts will be generated in an edge sensitive manner, i.e. when the associated status register transitions from 0 -> 1.

10 Table 60. USBDMask register format

Field Name	Bit(s)	Write	Description
		access	
CoreSuspendStickyEn	0	full	CoreSuspendSticky status interrupt enable.
CoreUSBResetStickyEn	1	full	CoreUSBResetSticky status interrupt enable.
CoreUSBSOFStickyEn	2	full	CoreUSBSOFSticky status interrupt enable.
CPUISITxBuffEmptyStickyEn	3	full	CPUISITxBuffEmptySticky status interrupt enable.
CPUEp0InBuffEmptyStickyEn	4	full	CPUEp0InBuffEmptySticky status interrupt enable.
CPUEp5InBuffEmptyStickyEn	5	full	CPUEp5InBuffEmptySticky status interrupt enable.

Ep0InNAKStickyEn	6	full	Ep0InNAKSticky status interrupt enable.
Ep5InNAKStickyEn	7	full	Ep5InNAKSticky status interrupt enable.
Ep0OutNAKStickyEn	8	full	Ep0OutNAKSticky status interrupt enable.
Ep1OutNAKStickyEn	9	full	Ep1OutNAKSticky status interrupt enable.
Ep2OutNAKStickyEn	10	full	Ep2OutNAKSticky status interrupt enable.
Ep3OutNAKStickyEn	11	full	Ep3OutNAKSticky status interrupt enable.
Ep4OutNAKStickyEn	. 12	full	Ep4OutNAKSticky status interrupt enable.
Ep1IrregPktStickyEn	13	full	Ep1IrregPktSticky status interrupt enable.
Ep2lrregPktStickyEn	14	full	Ep2IrregPktSticky status interrupt enable.
Ep3lrregPktStickyEn	15	full	Ep3IrregPktSticky status interrupt enable.
Ep4lrregPktStickyEn	16	full	Ep4lrregPktSticky status interrupt enable.
OutBuffOverFlowStickyEn	17	full	OutBuffOverFlowSticky status interrupt enable.
InBuffUnderRunStickyEn	18	full	InBuffUnderRunSticky status interrupt enable.

12.5.5.2.23 USBDDebug

This register is intended for debug purposes only. Contains non-sticky versions of all interrupt capable status bits, which are referred to as *dynamic* in the table.

Table 61. USBDDebug register format

Field Name	Bit(s)	write	Description
		access	
CoreTimeStamp	10:0	none	USB device core frame number.
CoreSuspend	11	none	Dynamic version of CoreSuspendSticky.
CoreUSBReset	12	none	Dynamic version of CoreUSBResetSticky.
CoreUSBSOF	13	none	Dynamic version of CoreUSBSOFSticky.
CPUISITxBuffEmpty	14	none	Dynamic version of CPUISITxBuffEmptySticky.
CPUEp0InBuffEmpty	15	none	Dynamic version of CPUEp0InBuffEmptySticky.
CPUEp5InBuffEmpty	16	none	Dynamic version of CPUEp5InBuffEmptySticky.
Ep0InNAK	17	none	Dynamic version of Ep0InNAKSticky.
Ep5InNAK	18	none	Dynamic version of Ep5InNAKSticky.
Ep0OutNAK	. 19	none	Dynamic version of Ep0OutNAKSticky.
Ep1OutNAK	20	none	Dynamic version of Ep1OutNAKSticky.
Ep2OutNAK	21	none	Dynamic version of Ep2OutNAKSticky.
Ep3OutNAK	22	none	Dynamic version of Ep3OutNAKSticky.
Ep4OutNAK	23	none	Dynamic version of Ep4OutNAKSticky.
Ep1lrregPkt	24	none	Dynamic version of Ep1IrregPktSticky.
Ep2IrregPkt	25	none	Dynamic version of Ep2IrregPktSticky.
Ep3lrregPkt	26	none	Dynamic version of Ep3IrregPktSticky.
Ep4IrregPkt	27	none	Dynamic version of Ep4IrregPktSticky.

OutBuffOverFlow	28	none	Dynamic version of OutBuffOverFlowSticky.
InBuffUnderRun	29	none	Dynamic version of InBuffUnderRunSticky.

12.5.5.2.24 USBHStatus

This register contains all status bits associated with the USBH. The field name extension *Sticky* implies that the status condition will remain registered until cleared by a CPU write.

Table 62. USBHStatus register format

٠	ı	ı	

Field Name	Bit(s)	Write access	Description
CorelRQSticky	0	clear	HC core IRQ interrupt flag. Sticky
			Set when HC core UHOSTC_IrqN output signal
			transitions from 0 -> 1. Refer to OHCl spec for details on
			HC interrupt processing.
			1 = IRQ interrupt from core.
			0 = default value.
CoreSMISticky	1	clear	HC core SMI interrupt flag. Sticky
			Set when HC core UHOSTC_SmiN output signal transi-
			tions from 0 -> 1. Refer to OHCl spec for details on HC
			interrupt processing.
			1 = SMI interrupt from HC.
			0 = default value.
CoreBuffAcc	2	none	HC core buffer access flag.
			HC core UHOSTC_BufAcc output signal. Indicates
			whether the HC is accessing a descriptor or a buffer in
			shared system memory.
			1 = buffer access
			0 = descriptor access.

12.5.5.2.25 USBHMask

This register serves as an interrupt mask for all USBH status conditions that can cause a CPU interrupt. All interrupts will be generated in an edge sensitive manner, i.e. when the associated status register transitions from 0 -> 1.

10 Table 63. USBHMask register format

Field Name	Bit(s)	Write access	Description
CorelRQIntEn	0	full	CoreIRQSticky status interrupt enable.
			1 = enable.
			0 = disable.
CoreSMIIntEn	1	full	CoreSMISticky status interrupt enable. 1 = enable.

		0 = disable.
 	-	

12.5.5.2.26 USBHDebug

This register is intended for debug purposes only. Contains non-sticky versions of all interrupt capable status bits, which are referred to as *dynamic* in the table.

Table 64. USBHDebug register format

5

10

	Bit(s)	write access	
CorelRQ	0	none	Dynamic version of CorelRQSticky.
CoreSMI	-	None	Dynamic version of CoreSMISticky.

12.5.5.2.27 |SICntrl

This register controls the general setup/configuration of the ISI.

Note that the reset value of this register allows the SoPEC to automatically become an ISIMaster (AutoMasterEnable = 1) if any USB packets are received on endpoints 2-4. On becoming an ISIMaster the ISIMasterSel bit is set and any USB or CPU packets destined for other ISI devices are transmitted. The CPU can override this capability at any time by clearing the AutoMasterEnable bit.

Table 65. ISICntrl register format

Field Name	Bit(s)	Write access	Description
TxEnable	0	Full	ISI transmit enable.
			Enables ISI transmission of long or ping packets. ACKs
			may still be transmitted when this bit is 0.
			This is cleared by transmit errors and needs to be
			restarted by the CPU.
			1 = Transmission enabled
			0 = Transmission disabled
RxEnable	1	Full	ISI receive enable.
			Enables ISI reception. This is can only be cleared by
			the CPU and it is only anticipated that reception will be
			disabled when the ISI in not in use and the ISI pins are
			being used by the GPIO for another purpose.
			1 = Reception enabled
			0 = Reception disabled
ISIMasterSel	2	Full	ISI master select.
			Determines whether the SoPEC is an ISIMaster or not
			1 = ISIMaster
			0 = ISISlave
AutoMasterEnable	3	Full	ISI auto master enable.

Enables the device to automatically become the
ISIMaster if activity is detected on USB endpoints2-4.
1 = auto-master operation enabled
0 = auto-master operation disabled

12.5.5.2.28

ISIId

Table 66. ISIId register format

Field Name	Bit(s)	Write	Description
		access	
ISIId	3:0	Full	ISIId for this SoPEC.
			SoPEC resets to being an ISISlave with ISIId0. 0xF (the
			broadcast ISIId) is an illegal value and should not be written
			to this register.

12.5.5.2.29

ISINumRetries

5

Table 67. ISINumRetries register format

Field Name	Bit(s)	Write	Description
		access	
ISINumRetries	3:0	Full	Number of ISI retransmissions to attempt in
			response to an inferred NAK before aborting a long
			packet transmission

12.5.5.2.30

ISIPingScheduleN

This register description applies to ISIPingSchedule0, ISIPingSchedule1 and ISIPingSchedule2.

10 Table 68. ISIPingScheduleN register format

Field Name	Bit(s)	Write	Description
		access	6 (2)
ISIPingSchedule	14:0	Full	Denotes which ISIIds will be receive ping packets.
	ŀ		Note that bit0 refers to ISIId0, bit1 to ISIId1bit14 to
			ISIId14.

12.5.5.2.31

ISITotalPeriod

Table 69. ISITotalPeriod register format

SITotalPeriod	3:0	Full	Reload value of the ISITotalPeriod counter
Field Name	Bit(s)	Write access	Description

15

12.5.5.2.32

ISILocalPeriod

Table 70. ISILocalPeriod register format

Field Name	Bit(s)	Write access	Description
ISILocalPeriod	3:0	Full	Reload value of the ISILocalPeriod counter

12.5.5.2.33

ISIIntStatus

The ISIIntStatus register contains status bits that are related to conditions that can cause an interrupt to the CPU, if the corresponding interrupt enable bits are set in the ISIMask register.

Table 71. ISIIntStatus register

5

Bit(s)	Write	Description
	access	
0	None	ISI transmit error flag. Sticky.
		Receiving ISI device would not accept the transmitted
		packet. Only set after NumRetries unsuccessful
		retransmissions. (excluding ping packets).
		This bit is cleared by the ISI after transmission has
		been re-enabled by the CPU setting the TxEnable bit
		of the ISICntrl register.
		1= transmit error.
		0 = default state.
1	Clear	ISI receive framing error flag. Sticky.
		This bit is set by the ISI when a framing error detected
		in the received packet, which can be caused by an
		incorrect Start or Stop field or by bit stuffing errors.
		1 = framing error detected.
		0 = default state.
2	Clear	ISI receive CRC error flag.
		This bit is set by the ISI when a CRC error is detected
		in an incoming packet. Other than dropping the
		errored packet ISI reception is unaffected by a CRC
		Error.
		1 = CRC error
		0 = default state.
3	Clear	ISI receive buffer over flow flag. Sticky.
		An overflow has occurred in the ISI receive buffer and
		a packet had to be dropped.
		1 = over flow condition detected.
		0 = default state.
	1	0 None 1 Clear

12.5.5.2.34

ISITxBuffStatus

The ISITxBuffStatus register contains status bits that are related to the ISI Tx buffer. This is a secondary status register and will not cause any interrupts to the CPU.

Table 72. ISITxBuffStatus register format

Field Name	Bit(s)	Write	Description
		access	
Entry0PktValid	0	None	ISI Tx buffer entry #0 packet valid flag.
			This flag will be set by the ISI when a valid ISI packet is
			written to entry #0 in the <i>ISITxBuff</i> for transmission over the
			ISI bus. A Tx packet is considered valid when it is 32 bytes
			in size and the ISI has written the packet header information
			to Entry0PktDesc, Entry0DestISIId and Entry0DestISISubId.
			1 = packet valid.
			0 = default value.
Entry0PktDesc	3:1	None	ISI Tx buffer entry #0 packet descriptor.
			PktDesc field as per Table for the packet entry #0 in the
			/S/TxBuff. Only valid when Entry0PktValid = 1.
Entry0DestISIId	7:4	None	ISI Tx buffer entry #0 destination ISI ID.
			Denotes the ISIId of the target SoPEC as per Table . Only
		:	valid when <i>Entry0PktValid</i> = 1.
Entry0DestISISubId	8	None	ISI Tx buffer entry #0 destination ISI sub ID.
			Indicates which DMAChannel on the target SoPEC that
			packet entry #0 in the ISITxBuff is destined for. Only valid
			when <i>Entry0PktValid</i> = 1.
			1 = DMAChannel1
			0 = DMAChannel0
Entry1PktValid	9	None	As per <i>Entry0PktValid</i> .
Entry1PktDesc	12:10	None	As per Entry0PktDesc.
Entry1DestISIId	16:13	None	As per Entry0DestISIId.
Entry1DestISISubId	17	None	As per Entry0DestISISubId.

12.5.5.2.35 ISIRxBuffStatus

5

The *ISIRxBuffStatus* register contains status bits that are related to the ISI Rx buffer. This is a secondary status register and will not cause any interrupts to the CPU.

Table 73. ISIRxBuffStatus register format

Field Name	Bit(s)	Write	Description
		access	
Entry0PktValid	0	None	ISI Rx buffer entry #0 packet valid flag.
			This flag will be set by the ISI when a valid ISI packet is
			received and written to entry #0 of the ISIRxBuff. A Rx
			packet is considered valid when it is 32 bytes in size and
			no framing or CRC errors were detected.

	· · · · ·	· ·	4 - volid modest
			1 = valid packet
			0 = default value
Entry0PktDesc	3:1	None	ISI Rx buffer entry #0 packet descriptor.
			PktDesc field as per Table for packet entry #0 of the
			ISIRxBuff. Only valid when Entry0PktValid = 1.
Entry0DestISIId	7:4	None	ISI Rx buffer 0 destination ISI ID.
			Denotes the ISIId of the target SoPEC as per Table . This
			should always correspond to the local SoPEC ISIId. Only
			valid when <i>Entry0PktValid</i> = 1.
Entry0DestISISubId	8	None	ISI Rx buffer 0 destination ISI sub ID.
			Indicates which DMAChannel on the target SoPEC that
			entry #0 of the ISIRxBuff is destined for. Only valid when
			Entry0PktValid = 1.
			1 = DMAChannel1
			0 = DMAChannel0
Entry1PktValid	9	None	As per <i>Entry0PktValid</i> .
Entry1PktDesc	12:10	None	As per Entry0PktDesc.
Entry1DestISIId	16:13	None	As per <i>Entry0DestISIId</i> .
Entry1DestISISubId	17	None	As per Entry0DestISISubId.

12.5.5.2.36 ISIMask register

An interrupt will be generated in an edge sensitive manner i.e. the ISI will generate an *isi_icu_irq* pulse each time a status bit goes high and the corresponding bit of the *ISIMask* register is enabled.

Table 74. ISIMask register

Field Name	Bit(s)	Write access	Description
TxErrorIntEn	0	Full	TxErrorSticky status interrupt enable. 1 = enable. 0 = disable.
RxFrameErrorIntEn	1	Full	RxFrameErrorSticky status interrupt enable. 1 = enable. 0 = disable.
RxCRCErrorIntEn	2	Fuli	RxCRCErrorSticky status interrupt enable. 1 = enable. 0 = disable.
RxBuffOverFlowIntEn	3	Full	RxBuffOverFlowSticky status interrupt enable. 1 = enable. 0 = disable.

12.5.5.2.37 ISISubIdNSeq

This register description applies to ISISubIdOSeq and ISISubIdOSeq.

Table 75. ISISubIdNSeq register format

Field Name Bit(s) Write		Write	Description
		access	
ISISubIdNSeq	0	Full	ISI sub ID channel N sequence bit.
			This bit may be initialised by the CPU but is
			updated by the ISI each time an error-free long
			packet is received.

5 12.5.5.2.38

ISISubIdSeqMask

Table 76. ISISubIdSeqMask register format

Field Name	Bit(s)	Write	Description	
2010/09/09		access		
ISISubIdSeq0Mask	0	Full	ISI sub ID channel 0 sequence bit mask.	
			Setting this bit ensures that the sequence bit will be	
			ignored for incoming packets for the ISISubId.	
			1 = ignore sequence bit.	
			0 = default state.	
ISISubIdSeq1Mask	1	Full	As per ISISubIdSeq0Mask.	

12.5.5.2.39

ISINumPins

Table 77. ISINumPins register format

10

15

Field Name	Bit(s)	Write access	Description
ISINumPins	0	Full	Select number of active ISI pins.
			1 = 4 pins
			0 = 2 pins

12.5.5.2.40

ISITurnAround

The ISI bus turnaround time will reset to its maximum value of 0xF to provide a safer starting mode for the ISI bus. This value should be set to a value that is suitable for the physical implementation of the ISI bus, i.e. the lowest turn around time that the physical implementation will allow without significant degradation of signal integrity.

Table 78. ISITurnAround register format

Field Name	Bit(s)	Write access	Description
ISITurnAround	3:0	Full	ISI bus turn around time in ISI clock
			cycles (32MHz).

12.5.5.2.41

ISIShortReplyWin

The ISI short packet reply window time will reset to its maximum value of 0x1F to provide a safer starting mode for the ISI bus. This value should be set to a value that will allow for expected frequency of bit stuffing and receiver response timing.

Table 79. ISIShortReplyWin register format

5

Field Name	Bit(s)	Write access	Description
ISIShortReplyWin	4:0	Full	ISI long packet reply window in ISI
			clock cycles (32MHz).

12.5.5.2.42 ISILongReplyWin

The ISI long packet reply window time will reset to its maximum value of 0x1FF to provide a safer starting mode for the ISI bus. This value should be set to a value that will allow for expected frequency of bit stuffing and receiver response timing.

10

Table 80. ISILongReplyWin register format

Field Name	Bit(s)	Write access	Description	
ISILongReplyWin	8:0	Full	ISI long packet reply window in ISI clock of (32MHz).	cycles
			(321/11/2).	

12.5.5.2.43 ISIDebug

This register is intended for debug purposes only. Contains non-sticky versions of all interrupt capable status bits, which are referred to as *dynamic* in the table.

15

25

Table 81. ISIDebug register format

Field Name	Bit(s)	Write access	Description
TxError	0	None	Dynamic version of TxErrorSticky.
RxFrameError	1	None	Dynamic version of RxFrameErrorSticky.
RxCRCError	2	None	Dynamic version of RxCRCErrorSticky.
RxBuffOverFlow	3	None	Dynamic version of RxBuffOverFlowSticky.

12.5.5.3 CPU Bus Interface

12.5.5.4 Control Core Logic

12.5.5.5 DIU Bus Interface

20 12.6 DMA REGS

All of the circular buffer registers are 256-bit word aligned as required by the DIU. The *DMAnBottomAdr* and *DMAnTopAdr* registers are inclusive i.e. the addresses contained in those registers form part of the circular buffer. The *DMAnCurrWPtr* always points to the next location the DMA manager will write to so interrupts are generated whenever the DMA manager reaches the address in either the *DMAnIntAdr* or *DMAnMaxAdr* registers rather than when it actually writes to these locations. It therefore can not write to the location in the *DMAnMaxAdr* register. SCB Map regs

The SCB map is configured by mapping a USB endpoint on to a data sink. This is performed on a endpoint basis i.e. each endpoint has a configuration register to allow its data sink be selected. Mapping an endpoint on to a data sink does not initiate any data flow - each endpoint/data sink needs to be enabled by writing to the appropriate configuration registers for the USBD, ISI and DMA manager.

13. General Purpose IO (GPIO)

13.1 OVERVIEW

5

10

30

The General Purpose IO block (GPIO) is responsible for control and interfacing of GPIO pins to the rest of the SoPEC system. It provides easily programmable control logic to simplify control of GPIO functions. In all there are 32 GPIO pins of which any pin can assume any output or input function.

Possible output functions are

- 4 Stepper Motor control Outputs
- 12 Brushless DC Motor Control Output (total of 2 different controllers each with 6 outputs)
- 4 General purpose high drive pulsed outputs capable of driving LEDs.
- 15 4 Open drain IOs used for LSS interfaces
 - 4 Normal drive low impedance IOs used for the ISI interface in Multi-SoPEC mode
 Each of the pins can be configured in either input or output mode, each pin is independently controlled. A programmable de-glitching circuit exists for a fixed number of input pins. Each input is a schmidt trigger to increase noise immunity should the input be used without the de-glitch circuit.
- The mapping of the above functions and their alternate use in a slave SoPEC to GPIO pins is shown in Table 82 below.

Table 82. GPIO pin type

GPIO pin(s)	Pin IO Type	Default Function
gpio[3:0]	Normal drive, low impedance IC (35 Ohm), Integrated pull-up resistor	Pins 1 and 0 in ISI Mode, pins 2 and 3 in input mode
gpio[7:4]	High drive, normal impedance IO (65 Ohm), intended for LED drivers	! •
gpio[31:8]	Normal drive, normal impedance IO (65 Ohm), no pull-up	Input Mode

13.2 Stepper Motor control

- The motor control pins can be directly controlled by the CPU or the motor control logic can be used to generate the phase pulses for the stepper motors. The controller consists of two central counters from which the control pins are derived. The central counters have several registers (see Table) used to configure the cycle period, the phase, the duty cycle, and counter granularity.
 - There are two motor master counters (0 and 1) with identical features. The period of the master counters are defined by the *MotorMasterClkPeriod[1:0]* and *MotorMasterClkSrc* registers i.e. both master counters are derived from the same *MotorMasterClkSrc*. The *MotorMasterClkSrc* defines

the timing pulses used by the master counters to determine the timing period. The MotorMasterClkSrc can select clock sources of 1μs,100μs,10ms and pclk timing pulses.

The *MotorMasterClkPeriod[1:0]* registers are set to the number of timing pulses required before the timing period re-starts. Each master counter is set to the relevant *MotorMasterClkPeriod* value and counts down a unit each time a timing pulse is received.

The master counters reset to *MotorMasterClkPeriod* value and count down. Once the value hits zero a new value is reloaded from the *MotorMasterClkPeriod[1:0]* registers. This ensures that no master clock glitch is generated when changing the clock period.

Each of the IO pins for the motor controller are derived from the master counters. Each pin has independent configuration registers. The *MotorMasterClkSelect[3:0]* registers define which of the two master counters to use as the source for each motor control pin. The master counter value is compared with the configured *MotorCtrlLow* and *MotorCtrlHigh* registers (bit fields of the *MotorCtrlConfig* register). If the count is equal to *MotorCtrlHigh* value the motor control is set to 1, if the count is equal to *MotorCtrlLow* value the motor control pin is set to 0.

- This allows the phase and duty cycle of the motor control pins to be varied at *pclk* granularity. The motor control generators keep a working copy of the *MotorCtrlLow, MotorCtrlHigh* values and update the configured value to the working copy when it is safe to do so. This allows the phase or duty cycle of a motor control pin to be safely adjusted by the CPU without causing a glitch on the output pin.
- Note that when reprogramming the *MotorCtrlLow, MotorCtrlHigh* registers to reorder the sequence of the transition points (e.g changing from low point less than high point to low point greater than high point and vice versa) care must still taken to avoid introducing glitching on the output pin.

13.3 LED CONTROL

5

LED lifetime and brightness can be improved and power consumption reduced by driving the LEDs with a pulsed rather than a DC signal. The source clock for each of the LED pins is a 7.8kHz (128μs period) clock generated from the 1μs clock pulse from the Timers block. The *LEDDutySelect* registers are used to create a signal with the desired waveform. Unpulsed operation of the LED pins can be achieved by using CPU IO direct control, or setting *LEDDutySelect* to 0. By default the LED pins are controlled by the LED control logic.

30 13.4 LSS INTERFACE VIA GPIO

In some SoPEC system configurations one or more of the LSS interfaces may not be used. Unused LSS interface pins can be reused as general IO pins by configuring the *IOModeSelect* registers. When a mode select register for a particular GPIO pin is set to 23,22,21,20 the GPIO pin is connected to LSS control IOs 3 to 0 respectively.

35 13.5 ISI INTERFACE VIA GPIO
In Multi-SoPEC mode the SCB block (in particular the ISI sub-block) requires direct access to and from the GPIO pins. Control of the ISI interface pins is determined by the IOModeSelect registers.
When a mode select register for a particular GPIO pin is set to 27,26,25,24 the GPIO pin connected to the ISI control bits 3 to 0 respectively. By default the GPIO pins 1 to 0 are directly controlled by
40 the ISI block.

In single SoPEC systems the pins can be re-used by the GPIO.

13.6 CPU GPIO CONTROL

5

10

35

The CPU can assume direct control of any (or all) of the IO pins individually. On a per pin basis the CPU can turn on direct access to the pin by configuring the *IOModeSelect* register to CPU direct mode. Once set the IO pin assumes the direction specified by the *CpuIODirection* register. When in output mode the value in register *CpuIOOut* will be directly reflected to the output driver. When in input mode the status of the input pin can be read by reading *CpuIOIn* register. When writing to the *CpuIOOut* register the value being written is XORed with the current value in *CpuIOOut*. The CPU can also read the status of the 10 selected de-glitched inputs by reading the *CpuIOInDeGlitch* register.

13.7 PROGRAMMABLE DE-GLITCHING LOGIC

Each IO pin can be filtered through a de-glitching logic circuit, the pin that the de-glitching logic is connected to is configured by the *InputPinSelect* registers. There are 10 de-glitching circuits, so a maximum of 10 input pin can be de-glitched at any time.

- The de-glitch circuit can be configured to sample the IO pin for a predetermined time before concluding that a pin is in a particular state. The exact sampling length is configurable, but each deglitch circuit must use one of two possible configured values (selected by *DeGlitchSelect*). The sampling length is the same for both high and low states. The *DeGlitchCount* is programmed to the number of system time units that a state must be valid for before the state is passed on. The time units are selected by *DeGlitchClkSel* and can be one of 1µs,100µs,10ms and *pclk* pulses.
 - For example if *DeGlitchCount* is set to 10 and *DeGlitchClkSel* set to 3, then the selected input pin must consistently retain its value for 10 system clock cycles (*pclk*) before the input state will be propagated from *CpulOln* to *CpulOlnDeglitch*.
 - 13.8 INTERRUPT GENERATION
- Any of the selected input pins (selected by *InputPinSelect*) can generate an interrupt from the raw or deglitched version of the input pin. There are 10 possible interrupt sources from the GPIO to the interrupt controller, one interrupt per input pin. The *InterruptSrcSelect* register determines whether the raw input or the deglitched version is used as the interrupt source.

The interrupt type, masking and priority can be programmed in the interrupt controller.

30 13.9 FREQUENCY ANALYSER

The frequency analyser measures the duration between successive positive edges on a selected input pin (selected by *InputPinSelect*) and reports the last period measured (*FreqAnaLastPeriod*) and a running average period (*FreqAnaAverage*).

The running average is updated each time a new positive edge is detected and is calculated by FreqAnaAverage = (FreqAnaAverage / 8) * 7 + FreqAnaLastPeriod / 8.

The analyser can be used with any selected input pin (or its deglitched form), but only one input at a time can be selected. The input is selected by the *FreqAnaPinSelect* (range of 0 to 9) and its deglitched form can be selected by *FreqAnaPinFormSelect*.

13.10 BRUSHLESS DC (BLDC) MOTOR CONTROLLERS

The GPIO contains 2 brushless DC (BLDC) motor controllers. Each controller consists of 3 hall inputs, a direction input, and six possible outputs. The outputs are derived from the input state and a pulse width modulated (PWM) input from the Stepper Motor controller, and is given by the truth table in Table 83.

5 Table 83. Truth Table for BLDC Motor Controllers

direction	hc	hb	ha	q6	q5	q4	q3	q2	q1
o	0	О	1	0	0	О	1	PWM	0
o	0	1	1	PWM	0	0	1	0	0
0	0	1	0	PWM	0	0	0	0	1
0	1	1	0	0	0	PWM	0	0	1
o	1	0	0	О	1	PWM	0	0	0
0	1	0	1	О	1	0	0	PWM	0
0	0	0	0	0	0	0	0	О	0
0	1	1	1	0	0	0	0	0	0
				- · · · · · · · - · · · · · · · · · · ·					
1	0	0	1	0	0	PWM	0	0	1
1	0	1	1	PWM	0	0	0	o	1
1	0	1	0	PWM	0	0	1	О	0
1	1	1	0	О	0	0	1	PWM	0
1	1	0	0	О	1	0	0	PWM	0
1	1	0	1	О	1	PWM	0	0	0
1	0	0	0	О	0	0	0	0	О
1	1	1	1	О	0	О	0	0	0

All inputs to a BLDC controller must be de-glitched. Each controller has its inputs hardwired to deglitch circuits. Controller 1 hall inputs are de-glitched by circuits 2 to 0, and its direction input is deglitched by circuit 3. Controller 2 inputs are de-glitched by circuits 6 to 4 for hall inputs and 7 for direction input.

Each controller also requires a PWM input. The stepper motor controller outputs are reused, output 0 is connected to BLDC controller 1, and output 1 to BLDC controller 2.

The controllers have two modes of operation, internal and external direction control (configured by *BLDCMode*). If a controller is in external direction mode the direction input is taken from a deglitched circuit, if it is in internal direction mode the direction input is configured by the *BLDCDirection* register.

The BLDC controller outputs are connected to the GPIO output pins by configuring the *IOModeSelect* register for each pin. e.g Setting the mode register to 8 will connect q1 Controller 1 to drive the pin.

13.11 IMPLEMENTATION

10

13.11.1 Definitions of I/O Table 84. I/O definition

Port name	Pins	1/0	Description
Clocks and Resets			
Pclk	1	ln	System Clock
prst_n	1	ln	System reset, synchronous active low
tim_pulse[2:0]	3	In	Timers block generated timing pulses.
			0 - 1 μs pulse
			1 - 100 μs pulse
			2 - 10 ms pulse
CPU Interface			
cpu_adr[8:2]	8	ln	CPU address bus. Only 7 bits are required to
			decode the address space for this block
cpu_dataout[31:0]	32	In	Shared write data bus from the CPU
gpio_cpu_data[31:0]	32	Out	Read data bus to the CPU
cpu_rwn	1	ln	Common read/not-write signal from the CPU
cpu_gpio_sel	1	ln	Block select from the CPU. When cpu_gpio_sel is
			high both <i>cpu_adr</i> and <i>cpu_dataout</i> are valid
gpio_cpu_rdy	1	Out	Ready signal to the CPU. When gpio_cpu_rdy is
			high it indicates the last cycle of the access. For a
			write cycle this means <i>cpu_dataout</i> has been
			registered by the GPIO block and for a read cycle
			this means the data on <i>gpio_cpu_data</i> is valid.
gpio_cpu_berr	1	Out	Bus error signal to the CPU indicating an invalid
			access.
gpio_cpu_debug_valid	1	Out	Debug Data valid on <i>gpio_cpu_data</i> bus. Active high
cpu_acode[1:0]	2	ln	CPU Access Code signals. These decode as
			follows:
			00 - User program access
			01 - User data access
			10 - Supervisor program access
			11 - Supervisor data access
IO Pins			
gpio_o[31:0]	32	Out	General purpose IO output to IO driver
gpio_i[31:0]	32	ln	General purpose IO input from IO receiver
gpio_e[31:0]	32	Out	General purpose IO output control. Active high
	<u> </u>		driving
GPIO to LSS			

lss_gpio_dout[1:0]	2	ln	LSS bus data output
			Bit 0 - LSS bus 0
			Bit 1 - LSS bus 1
gpio_lss_din[1:0]	2	Out	LSS bus data input
			Bit 0 - LSS bus 0
			Bit 1 - LSS bus 1
lss_gpio_e[1:0]	2	In	LSS bus data output enable, active high
			Bit 0 - LSS bus 0
			Bit 1 - LSS bus 1
lss_gpio_clk[1:0]	2	ln	LSS bus clock output
			Bit 0 - LSS bus 0
			Bit 1 - LSS bus 1
GPIO to ISI			
gpio_isi_din[1:0]	2	Out	Input data from IO receivers to ISI.
isi_gpio_dout[1:0]	2	In	Data output from ISI to IO drivers
isi_gpio_e[1:0]	2	In	GPIO ISI pins output enable (active high) from ISI
			interface
usbh_gpio_power_en	1	In	Port Power enable from the USB host core, active
			high
gpio_usbh_over_current	1	Out	Over current detect to the USB host core, active
			high
Miscellaneous	•	<u> </u>	
gpio_icu_irq[9:0]	10	Out	GPIO pin interrupts
gpio_cpr_wakeup	1	Out	SoPEC wakeup to the CPR block active high.
Debug			
debug_data_out[31:0]	32	In	Output debug data to be muxed on to the GPIO pins
debug_cntrl[31:0]	32	ln	Control signal for each GPIO bound debug data line
			indicating whether or not the debug data should be
			selected by the pin mux
<u> </u>			

13.11.2 Configuration registers

The configuration registers in the GPIO are programmed via the CPU interface. Refer to section 11.4.3 on page 69 for a description of the protocol and timing diagrams for reading and writing registers in the GPIO. Note that since addresses in SoPEC are byte aligned and the CPU only supports 32-bit register reads and writes, the lower 2 bits of the CPU address bus are not required to decode the address space for the GPIO. When reading a register that is less than 32 bits wide zeros should be returned on the upper unused bit(s) of *gpio_cpu_data*. Table 85 lists the configuration registers in the GPIO block

Table 85. GPIO Register Definition

Address GPIO_base +	Register	#bits	Reset		Description
0x000-0x07C	IOModeSelect[32x5	See		Specifies the mode of operation for each
	31:0]		Table f	or	GPIO pin. One 5 bit bus per pin.
			default va	alues	Possible assignment values and correspond
					controller outputs are as follows
					Value - Controlled by
					3 to 0 - Output, LED controller 4 to 1
					7 to 4 - Output Stepper Motor control 4-1
					13 to 8 - Output BLDC 1 Motor control 6-1
					19 to 14 - Output BLDC 2 Motor control 6-1
					23 to 20 - LSS control 4-1
					27 to 24 - ISI control 4-1
					28 - CPU Direct Control
					29 - USB power enable output
					30 - Input Mode
0x080-0xA4	InputPinSelect[10x5	0x00		Specifies which pins should be selected as
	9:0]				inputs. Used to select the pin source to the
					DeGlitch Circuits.
CPU IO Contr	ol		1		
0x0B0	CpulOUserMod	32	0x0000		User Mode Access Mask to CPU GPIO
	eMask		_0000		control register. When 1 user access is
					enabled. One bit per gpio pin. Enables
					access to CpulODirection, CpulOOut and
					CpulOIn in user mode.
0x0B4	CpulOSuperMo	32	0xFFFF		Supervisor Mode Access Mask to CPU
	deMask		_FFFF		GPIO control register. When 1 supervisor
					access is enabled. One bit per gpio pin.
					Enables access to CpulODirection,
	:				CpulOOut and CpulOIn in supervisor mode.
0x0B8	CpulODirection	32	0x0000		Indicates the direction of each IO pin, when
			_0000		controlled by the CPU
					0 - Indicates Input Mode
					1 - Indicates Output Mode
0x0BC	CpulOOut	32	0x0000		Value used to drive output pin in CPU direct
			_0000		mode.
					bits31:0 - Value to drive on output GPIO
					pins
					When written to the register assumes the

				new value XORed with the current value.
0x0C0	CpulOln	32	External p	inValue received on each input pin regardless
			value	of mode. Read Only register.
0x0C4	CpuDeGlitchUs	10	0x000	User Mode Access Mask to
	erModeMask			CpulOInDeglitch control register. When 1
				user access is enabled, otherwise bit reads
				as zero.
0x0C8	CpulOlnDeglitc	10	0x000	Deglitched version of selected input pins.
	h			The input pins are selected by the
				InputPinSelect register.
				Note that after reset this register will reflect
				the external pin values 256 <i>pclk</i> cycles after
				they have stabilized. Read Only register.
Deglitch contro	l ol		<u> </u>	
	DeGlitchCount[2x8	0xFF	Deglitch circuit sample count in
	1:0]			DeGlitchClkSrc selected units.
0x0D8-0x0DC	DeGlitchClkSrc	2x2	0x3	Specifies the unit use of the GPIO deglitch
	[1:0]			circuits:
	[· · · · ·]			0 - 1 μs pulse
				1 - 100 μs pulse
				2 - 10 ms pulse
				3 - pclk
0,050	DeGlitchSelect	10	0,000	
0x0E0	DeGlitchSelect	וו	0x000	Specifies which deglitch count
				(DeGlitchCount) and unit select
E				(DeGlitchClkSrc) should be used with each
				de-glitch circuit
				0 - Specifies DeGlitchCount[0] and
:				DeGlitchClkSrc[0]
				1 - Specifies DeGlitchCount[1] and
				DeGlitchClkSrc[1]
Motor Control		r	T	
		1	0x0	User Mode Access enable to Motor control
	ModeEnable			configuration registers. When 1 user access
			:	is enabled.
			:	Enables user access to
				MotorMasterClkPeriod, MotorMasterClkSrc,
				MotorDutySelect, MotorPhaseSelect,
				MotorMasterClockEnable, Motor-
	·			MasterClkSelect, BLDCMode and

				BLDCDirection registers
0x0E8-0x0EC	MotorMasterCl	2x16	0x0000	Specifies the motor controller master clock
	kPeriod[1:0]			periods in MotorMasterClkSrc selected units
0x0F0	MotorMasterCl	2	0x0	Specifies the unit use by the motor controller
	kSrc			master clock generator:
				0 - 1 μs pulse
				1 - 100 μs pulse
				2 - 10 ms pulse
				3 - pclk
0x0F4-0x100	MotorCtrlConfig	4x32	0x0000	Specifies the transition points in the clock
	[3:0]		_0000	period for each motor control pin. One
				register per pin
•.				bits 15:0 - MotorCtrlLow, high to low
				transition point
				bits 31:16 - <i>MotorCtrlHigh</i> , low to high
				transition point
0x104	MotorMasterCl	4	0x0	Specifies which motor master clock should
	kSelect			be used as a pin generator source
•				0 - Clock derived from MotorMasterClockPe-
				riod[0]
				1 -Clock derived from MotorMasterClockPe-
				riod[1]
0x108	MotorMasterCl	2	0x0	Enable the motor master clock counter.
	ockEnable			When 1 count is enabled
				Bit 0 - Enable motor master clock 0
				Bit 1 - Enable motor master clock 1
BLDC Motor (Controllers	<u> </u>		
0x10C	BLDCMode	2	0x0	Specifies the Mode of operation of the
				BLDC Controller. One bit per Controller.
				0- External direction control
				1- Internal direction control
0x110	BLDCDirection	2	0x0	Specifies the direction input of the BLDC
			1	controller. Only used when BLDC controller
				is an internal direction control mode. One bit
				per controller.
LED control		•		
0x114	LEDCtrlUserMo	4	0x0	User Mode Access enable to LED control
	deEnable			configuration registers. When 1 user access
				is enabled.

				One bit per LEDDutySelect select register.
0x118-0x124	LEDDutySelect	4x3	0x0	Specifies the duty cycle for each LED
	[3:0]			control output. See Figure 54 for encoding
				details. The LEDDutySelect[3:0] registers
				determine the duty cycle of the LED
				controller outputs
Frequency An	l nalyser		<u></u>	
0x130	FreqAnaUserM	1	0x0	User Mode Access enable to Frequency
	odeEnable			analyser configuration registers. When 1
				user access is enabled. Controls access to
				FreqAnaPinFormSelect,
		į		FreqAnaLastPeriod, FreqAnaAverage and
				FreqAnaCountInc.
0x134	FreqAnaPinSel	4	0x00	Selects which selected input should be used
	ect			for the frequency analyses.
0x138	FreqAnaPinFor	1	0x0	Selects if the frequency analyser should use
	mSelect			the raw input or the deglitched form.
				0 - Deglitched form of input pin
				1 - Raw form of input pin
0x13C	FreqAnaLastPe	16	0x0000	Frequency Analyser last period of selected
	riod			input pin.
0x140	FreqAnaAverag	16	0x0000	Frequency Analyser average period of
	е .			selected input pin.
0x144	FreqAnaCountI	20	0x0000 0	Frequency Analyser counter increment
:	nc			amount. For each clock cycle no edge is
				detected on the selected input pin the
				accumulator is incremented by this amount.
0x148	FreqAnaCount	32	0x0000	Frequency Analyser running counter
			_0000	(Working register)
Miscellaneous	S	L		
0x150	InterruptSrcSel	10	0x3FF	Interrupt source select.1 bit per selected
	ect			input. Determines whether the interrupt
				source is direct form the selected input pin
				or the deglitched version. Input pins are
				selected by the DeGlitchPinSelect register.
				0 - Selected input direct
				1 - Deglitched selected input
0x154	DebugSelect[8:	7	0x00	Debug address select. Indicates the address
	2]			of the register to report on the

				gpio_cpu_data bus when it is not otherwise
				being used.
0x158-0x15C	MotorMasterCo	2x16	0x0000	Motor master clock counter values.
	unt[1:0]			Bus 0 - Master clock count 0
				Bus 1 - Master clock count 1
				Read Only registers
0x160	WakeUpInputM	10	0x000	Indicates which deglitched inputs should be
	ask			considered to generate the CPR wakeup.
				Active high
0x164	WakeUpLevel	1	0	Defines the level to detect on the masked
				GPIO inputs to generate a wakeup to the
			1	CPR
				0 - Level 0
				1 - Level 1
0x168	USBOverCurre	4	0x00	Selects which deglitched input should be
	ntPinSelect			used for the USB over current detect.

13.11.2.1 Supervisor and user mode access

5

The configuration registers block examines the CPU access type (*cpu_acode* signal) and determines if the access is allowed to that particular register, based on configured user access registers. If an access is not allowed the GPIO will issue a bus error by asserting the *gpio_cpu_berr* signal.

All supervisor and user program mode accesses will result in a bus error.

Access to the CpulODirection, CpulOOut and CpulOIn is filtered by the CpulOUserModeMask and CpulOSuperModeMask registers. Each bit masks access to the corresponding bits in the CpulO* registers for each mode, with CpulOUserModeMask filtering user data mode access and

- 10 CpulOSuperModeMask filtering supervisor data mode access.
 - The addition of the *CpuIOSuperModeMask* register helps prevent potential conflicts between user and supervisor code read modify write operations. For example a conflict could exist if the user code is interrupted during a read modify write operation by a supervisor ISR which also modifies the *CpuIO** registers.
- An attempt to write to a disabled bit in user or supervisor mode will be ignored, and an attempt to read a disabled bit returns zero. If there are no user mode enabled bits then access is not allowed in user mode and a bus error will result. Similarly for supervisor mode.
 - When writing to the *CpulOOut* register, the value being written is XORed with the current value in the *CpulOOut* register, and the result is reflected on the GPIO pins.
- The pseudocode for determining access to the *CpulOOut* register is shown below. Similar code could be shown for the *CpulODirection* and *CpulOIn* registers. Note that when writing to *CpulODirection* data is deposited directly and not XORed with the existing data (as in the *CpulOOut* case).

```
if (cpu_acode == SUPERVISOR DATA MODE) then
                   // supervisor mode
                   if (CpuIOSuperModeMask[31:0] == 0 ) then
                      // access is denied, and bus error
 5
                      gpio cpu berr = 1

45
                The input selection pseudocode, for determining which pin connects to which de-
```

glitch circuit.

The *gpio_usbh_over_current* output to the USB core is driven by a selected deglitched input (configured by the *USBOverCurrentPinSelect* register).

```
index = USBOverCurrentPinSelect
gpio_usbh_over_current = cpu_io_in_deglitch[index]
```

10 13.11.5 Wakeup generator

5

The wakeup generator compares the deglitched inputs with the configured mask (WakeUpInputMask) and level (WakeUpLevel), and determines whether to generate a wakeup to the CPR block.

```
15
                  for (i = 0; i < 10; i++) {
                    if (wakeup_level = 0) then // level 0 active
                      wakeup
                                   wakeup
                                             OR
                                                 wakeup input mask[i]
                                                                               NOT
                                                                         AND
                  cpu_io_in_deglitch[i]
                    else
                                                 // level 1 active
20
                      wakeup
                                      wakeup
                                                OR
                                                      wakeup input mask[i]
                                                                               AND
                  cpu_io_in_deglitch[i]
                  // assign the output
                  gpio_cpr_wakeup = wakeup
```

25 13.11.6 LED pulse generator

The pulse generator logic consists of a 7-bit counter that is incremented on a 1µs pulse from the timers block (*tim_pulse[0]*). The LED control signal is generated by comparing the count value with the configured duty cycle for the LED (*led_duty_sel*).

```
The logic is given by:
```

13.11.7 Stepper Motor control

The motor controller consists of 2 counters, and 4 phase generator logic blocks, one per motor control pin. The counters decrement each time a timing pulse (*cnt_en*) is received. The counters start at the configured clock period value (*motor_mas_clk_period*) and decrement to zero. If the

counters are enabled (via *motor_mas_clk_enable*), the counters will automatically restart at the configured clock period value, otherwise they will wait until the counters are re-enabled.

The timing pulse period is one of *pclk*, 1μs, 100μs, 1ms depending on the *motor_mas_clk_sel* signal. The counters are used to derive the phase and duty cycle of each motor control pin.

```
// decrement logic
if (cnt_en == 1) then
    if ((mas_cnt == 0) AND (motor_mas_clk_enable == 1)) then
        mas_cnt = motor_mas_clk_period[15:0]

elsif ((mas_cnt == 0) AND (motor_mas_clk_enable == 0)) then
        mas_cnt = 0
    else
        mas_cnt --
else // hold the value

mas_cnt = mas_cnt
```

The phase generator block generates the motor control logic based on the selected clock generator (motor_mas_clk_sel) the motor control high transition point (curr_motor_ctrl_high) and the motor control low transition point (curr_motor_ctrl_low).

The phase generator maintains current copies of the *motor_ctrl_config* configuration value (*motor_ctrl_config[31:16]* becomes *curr_motor_ctrl_high* and *motor_ctrl_config[15:0]* becomes *curr_motor_ctrl_low*). It updates these values to the current register values when it is safe to do so without causing a glitch on the output motor pin.

Note that when reprogramming the *motor_ctrl_config* register to reorder the sequence of the transition points (e.g changing from low point less than high point to low point greater than high point and vice versa) care must taken to avoid introducing glitching on the output pin.

There are 4 instances one per motor control pin.

The logic is given by:

5

25

```
// select the input counter to use
30
                 if (motor mas clk sel == 1) then
                   count = mas_cnt[1]
                 else
                   count = mas_cnt[0]
                 // Generate the phase and duty cycle
35
                 if (count == curr motor ctrl low) then
                   motor ctrl = 0
                 elsif (count == curr motor ctrl high) then
                   motor ctrl = 1
                 else
40
                   motor_ctrl = motor_ctrl // remain the same
                 // update the current registers at period boundary
                 if (count == 0) then
```

```
curr_motor_ctrl_high = motor_ctrl_config[31:16]  //
update to new high value
  curr_motor_ctrl_low = motor_ctrl_config[15:0]  //
update to new high value
```

5

13.11.8 Input deglitch

The input deglitch logic rejects input states of duration less than the configured number of time units (deglitch_cnt), input states of greater duration are reflected on the output cpu_io_in_deglitch. The time units used (either pclk, 1μs, 100μs, 1ms) by the deglitch circuit is selected by the

10 deglitch clk src bus.

There are 2 possible sets of deglitch_cnt and deglitch_clk_src that can be used to deglitch the input pins. The values used are selected by the deglitch_sel signal.

There are 10 deglitch circuits in the GPIO. Any GPIO pin can be connected to a deglitch circuit. Pins are selected for deglitching by the *InputPinSelect* registers.

Each selected input can be used to generate an interrupt. The interrupt can be generated from the raw input signal (deglitch_input) or a deglitched version of the input (cpu_io_in_deglitch). The interrupt source is selected by the interrupt_src_select signal.

The counter logic is given by

13.11.9 Frequency Analyser

The frequency analyser block monitors a selected deglitched input (cpu_io_in_deglitch) or a direct selected input (deglitch_input) and detects positive edges. The selected input is configured by FreqAnaPinSelect and FreqAnaPinFormSel registers. Between successive positive edges detected on the input it increments a counter (FreqAnaCount) by a programmed amount (FreqAnaCountInc) on each clock cycle. When a positive edge is detected the FreqAnaLastPeriod register is updated with the top 16 bits of the counter and the counter is reset. The frequency analyser also maintains a running average of the FreqAnaLastPeriod register. Each time a positive edge is detected on the input the FreqAnaAverage register is updated with the new calculated FreqAnaLastPeriod. The average is calculated as 7/8 the current value plus 1/8 of the new value. The FreqAnaLastPeriod, FreqAnaCount and FreqAnaAverage registers can be written to by the CPU.

40 The pseudocode is given by

```
freq_ana_lastperiod[15:0] = freq_ana_count[31:16]
                   freq ana average[15:0]
                                                       freq_ana_average[15:0]
                 freq ana average[15:3]
5
                 freq ana lastperiod[15:3]
                   freq_ana_count[15:0]
                 else
                   freq_ana_count[31:0]
                                                         freq ana count[31:0]
                 freq_ana_count_inc[19:0]
10
                 // implement the configuration register write
                 if (wr_last_en == 1) then
                   freq ana lastperiod = wr data
                 elsif (wr_average_en == 1 ) then
                   freq_ana_average = wr data
15
                 elsif (wr_freq_count_en == 1) then
                   freq_ana_count = wr_data
```

13.11.10 BLDC Motor Controller

The BLDC controller logic is identical for both instances, only the input connections are different.

The logic implements the truth table shown in Table . The six *q* outputs are combinationally based on the *direction*, *ha*, *hb*, *hc* and *pwm* inputs. The direction input has 2 possible sources selected by the mode, the pseudocode is as follows

14 Interrupt Controller Unit (ICU)

25

30

The interrupt controller accepts up to N input interrupt sources, determines their priority, arbitrates based on the highest priority and generates an interrupt request to the CPU. The ICU complies with the interrupt acknowledge protocol of the CPU. Once the CPU accepts an interrupt (i.e. processing of its service routine begins) the interrupt controller will assert the next arbitrated interrupt if one is pending.

Each interrupt source has a fixed vector number N, and an associated configuration register,

35 IntReg[N]. The format of the IntReg[N] register is shown in Table 87 below.

Table 87. IntReg[N] register format

Field	bit(s)	Description			
Priority	3:0	Interrupt priority			
Туре	5:4	Determines the triggering conditions for the interrupt			
		00 - Positive edge			
		10 - Negative edge			

		01 - Positive level 11 - Negative level
Mask	6	Mask bit. 1 - Interrupts from this source are enabled,
		0 - Interrupts from this source are disabled. Note that there may be additional masks in operation at the source of the interrupt.
Reserved	31:7	Reserved. Write as 0.

Once an interrupt is received the interrupt controller determines the priority and maps the programmed priority to the appropriate CPU priority levels, and then issues an interrupt to the CPU. The programmed interrupt priority maps directly to the LEON CPU interrupt levels. Level 0 is no interrupt. Level 15 is the highest interrupt level.

14.1 INTERRUPT PREEMPTION

5

With standard LEON pre-emption an interrupt can only be pre-empted by an interrupt with a higher priority level. If an interrupt with the same priority level (1 to 14) as the interrupt being serviced becomes pending then it is not acknowledged until the current service routine has completed.

- Note that the level 15 interrupt is a special case, in that the LEON processor will continue to take level 15 interrupts (i.e re-enter the ISR) as long as level 15 is asserted on the *icu_cpu_ilevel*. Level 0 is also a special case, in that LEON consider level 0 interrupts as no interrupt, and will not issue an acknowledge when level 0 is presented on the *icu_cpu_ilevel* bus.
- Thus when pre-emption is required, interrupts should be programmed to different levels as interrupt priorities of the same level have no guaranteed servicing order. Should several interrupt sources be programmed with the same priority level, the lowest value interrupt source will be serviced first and so on in increasing order.
 - The interrupt is directly acknowledged by the CPU and the ICU automatically clears the pending bit of the lowest value pending interrupt source mapped to the acknowledged interrupt level.
- All interrupt controller registers are only accessible in supervisor data mode. If the user code wishes to mask an interrupt it must request this from the supervisor and the supervisor software will resolve user access levels.

14.2 INTERRUPT SOURCES

The mapping of interrupt sources to interrupt vectors (and therefore *IntReg[N]* registers) is shown in Table 88 below. Please refer to the appropriate section of this specification for more details of the interrupt sources.

Table 88. Interrupt sources vector table

Vector	Source	Description
o	Timers	WatchDog Timer Update request
1	Timers	Generic Timer 1 interrupt

2	Timers	Generic Timer 2 interrupt			
3	PCU	PEP Sub-system Interrupt- TE finished band			
4	PCU	PEP Sub-system Interrupt- LBD finished band			
5	PCU	PEP Sub-system Interrupt- CDU finished band			
6	PCU	PEP Sub-system Interrupt- CDU error			
7	PCU	PEP Sub-system Interrupt- PCU finished band			
8	PCU	PEP Sub-system Interrupt- PCU Invalid address interrupt			
9	PHI	PEP Sub-system Interrupt- PHI Line Sync Interrupt			
10	PHI	PEP Sub-system Interrupt- PHI Buffer underrun			
11	PHI	PEP Sub-system Interrupt- PHI Page finished			
12	PHI	PEP Sub-system Interrupt- PHI Print ready			
13	SCB	USB Host interrupt			
14	SCB	USB Device interrupt			
15	SCB	ISI interrupt			
16	SCB	DMA interrupt			
17	LSS	LSS interrupt, LSS interface 0 interrupt request			
18	LSS	LSS interrupt, LSS interface 1 interrupt request			
19-28	GPIO	GPIO general purpose interrupts

14.3 IMPLEMENTATION

14.3.1 Definitions of I/O

Table 89. Interrupt Controller Unit I/O definition

Port name	Pins	1/0	Description
Clocks and Resets			
Pclk	1	ln	System Clock
prst_n	1	ln	System reset, synchronous active low
CPU interface		<u></u>	
cpu_adr[7:2]	6	ln	CPU address bus. Only 6 bits are required to
			decode the address space for the ICU block
cpu_dataout[31:0]	32	In	Shared write data bus from the CPU
icu_cpu_data[31:0]	32	Out	Read data bus to the CPU
cpu_rwn	1	ln	Common read/not-write signal from the CPU
cpu_icu_sel	1	ln	Block select from the CPU. When cpu_icu_sel is
			high both <i>cpu_adr</i> and <i>cpu_dataout</i> are valid
icu_cpu_rdy	1	Out	Ready signal to the CPU. When icu_cpu_rdy is
			high it indicates the last cycle of the access. For
			a write cycle this means cpu_dataout has been

			registered by the ICU block and for a read cycle
			this means the data on <i>icu_cpu_data</i> is valid.
icu_cpu_ilevel[3:0]	4	Out	
icu_cpu_iievei[3.0]	ľ	Out	Indicates the priority level of the current active interrupt.
cpu_iack	1 -	in	Interrupt request acknowledge from the LEON
opu_iusi.			core.
cpu_icu_ilevel[3:0]	4	In	Interrupt acknowledged level from the LEON
			core .
icu_cpu_berr	1	Out	Bus error signal to the CPU indicating an invalid
			access.
cpu_acode[1:0]	2	In	CPU Access Code signals. These decode as
			follows:
			00 - User program access
			01 - User data access
			10 - Supervisor program access
			11 - Supervisor data access
icu_cpu_debug_valid	1	Out	Debug Data valid on <i>icu_cpu_data</i> bus. Active
			high
Interrupts	-		
tim_icu_wd_irq	1	ln	Watchdog timer interrupt signal from the Timers
			block
tim_icu_irq[2:0]	3	In	Generic timer interrupt signals from the Timers
			block
gpio_icu_irq[9:0]	10	In	GPIO pin interrupts
usb_icu_irq[1:0]	2	In	USB host and device interrupts from the SCB
			Bit 0 - USB Host interrupt
			Bit 1 - USB Device interrupt
isi_icu_irq	1	In	ISI interrupt from the SCB
dma_icu_irq	1	ln	DMA interrupt from the SCB
lss_icu_irq[1:0]	2	ln	LSS interface interrupt request
cdu_finishedband	1	ln	Finished band interrupt request from the CDU
cdu_icu_jpegerror	1	In	JPEG error interrupt from the CDU
lbd_finishedband	1	ln	Finished band interrupt request from the LBD
te_finishedband	1	In	Finished band interrupt request from the TE
pcu_finishedband	1	ln	Finished band interrupt request from the PCU
pcu_icu_address_invalid	1	ln	Invalid address interrupt request from the PCU
phi_icu_underrun	1	ln	Buffer underrun interrupt request from the PHI
phi_icu_page_finish	1	In	Page finished interrupt request from the PHI
	I.		1 3

phi_icu_linesync_int	1	ln	Line sync interrupt request from the PHI
	l		

14.3.2 Configuration registers

5

The configuration registers in the ICU are programmed via the CPU interface. Refer to section 11.4 on page 69 for a description of the protocol and timing diagrams for reading and writing registers in the ICU. Note that since addresses in SoPEC are byte aligned and the CPU only supports 32-bit register reads and writes, the lower 2 bits of the CPU address bus are not required to decode the address space for the ICU. When reading a register that is less than 32 bits wide zeros should be returned on the upper unused bit(s) of *icu_pcu_data*. Table 90 lists the configuration registers in the ICU block.

The ICU block will only allow supervisor data mode accesses (i.e. cpu_acode[1:0] = SUPERVISOR_DATA). All other accesses will result in icu_cpu_berr being asserted.

Table 90. ICU Register Map

Address ICU_base +	Register	#bits	Reset	Description
0x00 - 0x74	IntReg[29:0]	30x7	0x00	Interrupt vector configuration register
0x88	IntClear	30	0x0000 _0000	Interrupt pending clear register. If written with a one it clears corresponding interrupt Bits[30:0] - Interrupts sources 30 to 0 (Reads as zero)
0x90	IntPending	30	0x0000 _0000	Interrupt pending register. (Read Only) Bits[30:0]- Interrupts sources 30 to 0
0xA0	IntSource	5	0x1F	Indicates the interrupt source of the last acknowledged interrupt. The <i>NoInterrupt</i> value is defined as all bits set to one. (Read Only)
0xC0	DebugSelect[7:2]	6	0x00	Debug address select. Indicates the address of the register to report on the <i>icu_cpu_data</i> bus when it is not otherwise being used.

14.3.3 ICU partition

15

20

14.3.4 Interrupt detect

The ICU contains multiple instances of the interrupt detect block, one per interrupt source. The interrupt detect block examines the interrupt source signal, and determines whether it should generate request pending (*int_pend*) based on the configured interrupt type and the interrupt source conditions. If the interrupt is not masked the interrupt will be reflected to the interrupt arbiter via the *int_active* signal. Once an interrupt is pending it remains pending until the interrupt is accepted by the CPU or it is level sensitive and gets removed. Masking a pending interrupt has the effect of removing the interrupt from arbitration but the interrupt will still remain pending.

When the CPU accepts the interrupt (using the normal ISR mechanism), the interrupt controller automatically generates an interrupt clear for that interrupt source (cpu_int_clear). Alternatively if the interrupt is masked, the CPU can determine pending interrupts by polling the IntPending registers. Any active pending interrupts can be cleared by the CPU without using an ISR via the IntClear registers.

Should an interrupt clear signal (either from the interrupt clear unit or the CPU) and a new interrupt condition happen at the same time, the interrupt will remain pending. In the particular case of a level sensitive interrupt, if the level remains the interrupt will stay active regardless of the clear signal.

The logic is shown below:

5

```
10
                 mask
                               = int_config[6]
                 type
                               = int config[5:4]
                 int pend
                                = last int pend
                                                             // the last pending
                 interrupt
                 // update the pending FF
15
                 // test for interrupt condition
                 if (type == NEG LEVEL) then
                    int_pend = NOT(int_src)
                 elsif (type == POS_LEVEL)
                    int pend = int src
20
                 elsif
                         ((type ==
                                     POS EDGE
                                                     AND
                                                           (int src
                                                                         1)
                                                                              AND
                  (last int src == 0))
                    int pend = 1
                 elsif
                         ((type ==
                                      NEG EDGE
                                                     AND
                                                           (int src
                                                 )
                                                                         0)
                                                                              AND
                  (last_int_src == 1))
25
                    int pend = 1
                 elsif ((int clear == 1 )OR (cpu int clear==1)) then
                    int pend = 0
                    int_pend = last_int_pend // stay the same as before
30
                 // mask the pending bit
                 if (mask == 1) then
                    int_active = int pend
                 else
                    int_active = 0
35
                 // assign the registers
                 last_int_src = int_src
                 last_int_pend = int_pend
```

14.3.5 Interrupt arbiter

The interrupt arbiter logic arbitrates a winning interrupt request from multiple pending requests

40 based on configured priority. It generates the interrupt to the CPU by setting *icu_cpu_ilevel* to a

non-zero value. The priority of the interrupt is reflected in the value assigned to *icu_cpu_ilevel*, the
higher the value the higher the priority, 15 being the highest, and 0 considered no interrupt.

```
// arbitrate with the current winner
int_ilevel = 0
```

10 14.3.6 Interrupt clear unit

15

20

40

The interrupt clear unit is responsible for accepting an interrupt acknowledge from the CPU, determining which interrupt source generated the interrupt, clearing the pending bit for that source and updating the *IntSource* register.

When an interrupt acknowledge is received from the CPU, the interrupt clear unit searches through each interrupt source looking for interrupt sources that match the acknowledged interrupt level (cpu_icu_ilevel) and determines the winning interrupt (lower interrupt source numbers have higher priority). When found the interrupt source pending bit is cleared and the IntSource register is updated with the interrupt source number.

The LEON interrupt acknowledge mechanism automatically disables all other interrupts temporarily until it has correctly saved state and jumped to the ISR routine. It is the responsibility of the ISR to re-enable the interrupts. To prevent the *IntSource* register indicating the incorrect source for an interrupt level, the ISR must read and store the *IntSource* value before re-enabling the interrupts via the Enable Traps (ET) field in the Processor State Register (PSR) of the LEON.

See section 11.9 on page 104 for a complete description of the interrupt handling procedure.

After reset the state machine remains in *Idle* state until an interrupt acknowledge is received from the CPU (indicated by *cpu_iack*). When the acknowledge is received the state machine transitions to the *Compare* state, resetting the source counter (*cnt*) to the number of interrupt sources.

While in the *Compare* state the state machine cycles through each possible interrupt source in decrementing order. For each active interrupt source the programmed priority (*int_priority[cnt][3:0]*) is compared with the acknowledged interrupt level from the CPU (*cpu_icu_ilevel*), if they match then

the interrupt is considered the new winner. This implies the last interrupt source checked has the highest priority, e.g interrupt source zero has the highest priority and the first source checked has the lowest priority. After all interrupt sources are checked the state machine transitions to the *IntClear* state, and updates the *int_source* register on the transition.

35 Should there be no active interrupts for the acknowledged level (e.g. a level sensitive interrupt was removed), the *IntSource* register will be set to *NoInterrupt*. *NoInterrupt* is defined as the highest possible value that *IntSource* can be set to (in this case 0x1F), and the state machine will return to *Idle*.

The exact number of compares performed per clock cycle is dependent the number of interrupts, and logic area to logic speed trade-off, and is left to the implementer to determine. A comparison of

all interrupt sources must complete within 8 clock cycles (determined by the CPU acknowledge hardware).

When in the *IntClear* state the state machine has determined the interrupt source to clear (indicated by the *int_source* register). It resets the pending bit for that interrupt source, transitions back to the *Idle* state and waits for the next acknowledge from the CPU.

The minimum time between successive interrupt acknowledges from the CPU is 8 cycles.

15 Timers Block (TIM)

The Timers block contains general purpose timers, a watchdog timer and timing pulse generator for use in other sections of SoPEC.

10 15.1 WATCHDOG TIMER

5

15

20

30

35

The watchdog timer is a 32 bit counter value which counts down each time a timing pulse is received. The period of the timing pulse is selected by the *WatchDogUnitSel* register. The value at any time can be read from the *WatchDogTimer* register and the counter can be reset by writing a non-zero value to the register. When the counter transitions from 1 to 0, a system wide reset will be triggered as if the reset came from a hardware pin.

The watchdog timer can be polled by the CPU and reset each time it gets close to 1, or alternatively a threshold (*WatchDogIntThres*) can be set to trigger an interrupt for the watchdog timer to be serviced by the CPU. If the *WatchDogIntThres* is set to N, then the interrupt will be triggered on the N to N-1 transition of the *WatchDogTimer*. This interrupt can be effectively masked by setting the threshold to zero. The watchdog timer can be disabled, without causing a reset, by writing zero to the *WatchDogTimer* register.

15.2 TIMING PULSE GENERATOR

The timing block contains a timing pulse generator clocked by the system clock, used to generate timing pulses of programmable periods. The period is programmed by accessing the

25 TimerStartValue registers. Each pulse is of one system clock duration and is active high, with the pulse period accurate to the system clock frequency. The periods after reset are set to 1us, 100us and 100 ms.

The timing pulse generator also contains a 64-bit free running counter that can be read or reset by accessing the *FreeRunCount* registers. The free running counter can be used to determine elapsed time between events at system clock accuracy or could be used as an input source in low-security random number generator.

15.3 GENERIC TIMERS

SoPEC contains 3 programmable generic timing counters, for use by the CPU to time the system. The timers are programmed to a particular value and count down each time a timing pulse is received. When a particular timer decrements from 1 to 0, an interrupt is generated. The counter can be programmed to automatically restart the count, or wait until re-programmed by the CPU. At any time the status of the counter can be read from *GenCntValue*, or can be reset by writing to *GenCntValue* register. The auto-restart is activated by setting the *GenCntAuto* register, when activated the counter restarts at *GenCntStartValue*. A counter can be stopped or started at any

time, without affecting the contents of the *GenCntValue* register, by writing a 1 or 0 to the relevent *GenCntEnable* register.

15.4 IMPLEMENTATION

15.4.1 Definitions of I/O

5

Table 91. Timers block I/O definition

Port name	Pins	1/0	Description	
Clocks and Resets		<u> </u>		
Pclk	1	ln	System Clock	
prst_n	1	ln	System reset, synchronous active low	
tim_pulse[2:0]	3	Out	Timers block generated timing pulses, each one pclk	
			wide	
			0 - Nominal 1μs pulse	
			1 - Nominal 100 μs pulse	
			2 - Nominal 10ms pulse	
CPU interface		<u> </u>	<u> </u>	
cpu_adr[6:2]	5	ln	CPU address bus. Only 5 bits are required to decode	
			the address space for the ICU block	
cpu_dataout[31:0]	32	In	Shared write data bus from the CPU	
tim_cpu_data[31:0]	32	Out	Read data bus to the CPU	
cpu_rwn	1	In	Common read/not-write signal from the CPU	
cpu_tim_sel	1	ln	Block select from the CPU. When cpu_tim_sel is high	
			both <i>cpu_adr</i> and <i>cpu_dataout</i> are valid	
tim_cpu_rdy	1	Out	Ready signal to the CPU. When tim_cpu_rdy is high	
			it indicates the last cycle of the access. For a write	
			cycle this means cpu_dataout has been registered by	
		1	the TIM block and for a read cycle this means the	
			data on <i>tim_cpu_data</i> is valid.	
tim_cpu_berr	1	Out	Bus error signal to the CPU indicating an invalid	
			access.	
cpu_acode[1:0]	2	In	CPU Access Code signals. These decode as follows:	
			00 - User program access	
			01 - User data access	
			10 - Supervisor program access	
			11 - Supervisor data access	
tim_cpu_debug_valid	1	Out	Debug Data valid on tim_cpu_data bus. Active high	
Miscellaneous				
tim_icu_wd_irq	1	Out	Watchdog timer interrupt signal to the ICU block	
tim_icu_irq[2:0]	3	Out	Generic timer interrupt signals to the ICU block	

tim_cpr_reset_n	1	Out	Watch dog timer system reset.
-----------------	---	-----	-------------------------------

15.4.2 Timers sub-block partition

15.4.3 Watchdog timer

5

The watchdog timer counts down from pre-programmed value, and generates a system wide reset when equal to one. When the counter passes a pre-programmed threshold (wdog_tim_thres) value an interrupt is generated (tim_icu_wd_irq) requesting the CPU to update the counter. Setting the counter to zero disables the watchdog reset. In supervisor mode the watchdog counter can be written to or read from at any time, in user mode access is denied. Any accesses in user mode will generate a bus error.

```
10
                  The counter logic is given by
                  if (wdog wen == 1) then
                    wdog_tim_cnt = write_data
                                                     // load new data
                  elsif ( wdog tim cnt == 0) then
                    wdog tim cnt = wdog tim cnt
                                                    // count disabled
15
                  elsif ( cnt_en == 1 ) then
                    wdog tim cnt--
                  else
                    wdog tim cnt = wdog tim cnt
                  The timer decode logic is
20
                  if (( wdog_tim_cnt == wdog_tim_thres) AND (wdog_tim_cnt != 0
                  )AND (cnt en == 1)) then
                    tim icu wd irq = 1
                  else
                    tim_icu wd_irq = 0
25
                  // reset generator logic
                  if (wdog tim cnt == 1) AND (cnt_en == 1) then
                    tim cpr reset n = 0
                  else
                    tim cpr reset n = 1
30
```

15.4.4 Generic timers

35

The generic timers block consists of 3 identical counters. A timer is set to a pre-configured value (*GenCntStartValue*) and counts down once per selected timing pulse (*gen_unit_sel*). The timer can be enabled or disabled at any time (*gen_tim_en*), when disabled the counter is stopped but not cleared. The timer can be set to automatically restart (*gen_tim_auto*) after it generates an interrupt. In supervisor mode a timer can be written to or read from at any time, in user mode access is determined by the *GenCntUserModeEnable* register settings.

```
The counter logic is given by

if (gen_wen == 1) then

gen_tim_cnt = write_data

elsif (( cnt_en == 1 )AND (gen_tim_en == 1 )) then
```

```
if ( gen_tim_cnt == 1) OR ( gen_tim_cnt == 0)
                                                                        then
                                                                               //
                 counter may need re-starting
                      if (gen_tim_auto == 1) then
                        gen_tim_cnt = gen tim cnt st value
 5
                      else
                        gen_tim_cnt = 0
                                                                          // hold
                 count at zero
                    else
                      gen_tim_cnt--
10
                 else
                    gen_tim_cnt = gen_tim_cnt
                 The decode logic is
                 if (gen_tim_cnt == 1)AND ( cnt_en == 1 )AND (gen_tim_en == 1
                 ) then
15
                    tim icu irq = 1
                 else
                    tim_icu_irq = 0
```

15.4.5 Timing pulse generator

The timing pulse generator contains a general free running 64-bit timer and 3 timing pulse generators producing timing pulses of one cycle duration with a programmable period. The period is programmed by changed the *TimerStartValue* registers, but have a nominal starting period of 1µs, 100µs and 1ms. In supervisor mode the free running timer register can be written to or read from at any time, in user mode access is denied. The status of each of the timers can be read by accessing the *PulseTimerStatus* registers in supervisor mode. Any accesses in user mode will result in a bus error.

15.4.5.1 Free Run Timer

20

25

30

The increment logic block increments the timer count on each clock cycle. The counter wraps around to zero and continues incrementing if overflow occurs. When the timing register (FreeRunCount) is written to, the configuration registers block will set the free_run_wen high for a clock cycle and the value on write_data will become the new count value. If free_run_wen[1] is 1 the higher 32 bits of the counter will be written to, otherwise if free_run_wen[0] the lower 32 bits are written to. It is the responsibility of software to handle these writes in a sensible manner.

The increment logic is given by

40 15.4.5.2 Pulse Timers

The pulse timer logic generates timing pulses of 1 clock cycle length and programmable period. Nominally they generate pulse periods of 1µs, 100µs and 1ms. The logic for timer 0 is given by:

```
// Nominal lus generator
```

```
if (pulse_0_cnt == 0 ) then
                    pulse_0_cnt = timer start value[0]
                     tim pulse[0] = 1
                  else
 5
                    pulse 0 cnt --
                    tim pulse[0] = 0
     The logic for timer 1 is given by:
                  // 100us generator
10
                  if ((pulse 1 cnt == 0) AND (tim pulse[0] == 1)) then
                    pulse_1_cnt = timer_start_value[1]
                    tim pulse[1] = 1
                  elsif (tim pulse[0] == 1) then
                    pulse 1 cnt --
15
                    tim pulse[1] = 0
                    pulse_1_cnt = pulse_1_cnt
                    tim pulse[1] = 0
20
     The logic for the timer 2 is given by:
                  // 10ms generator
                  if ((pulse 2 cnt == 0 ) AND (tim pulse[1] == 1)) then
                    pulse_2_cnt = timer start value[2]
                    tim pulse[2] = 1
25
                  elsif (tim_pulse[1] == 1) then
                    pulse 2 cnt --
                    tim pulse[2] = 0
                  else
                    pulse_2_cnt = pulse 2 cnt
30
                    tim_pulse[2] = 0
```

15.4.6 Configuration registers

The configuration registers in the TIM are programmed via the CPU interface. Refer to section 11.4.3 on page 69 for a description of the protocol and timing diagrams for reading and writing registers in the TIM. Note that since addresses in SoPEC are byte aligned and the CPU only supports 32-bit register reads and writes, the lower 2 bits of the CPU address bus are not required to decode the address space for the TIM. When reading a register that is less than 32 bits wide zeros should be returned on the upper unused bit(s) of *tim_pcu_data*. Table 92 lists the configuration registers in the TIM block.

Table 92. Timers Register Map

15.4.6.1 Supervisor and user mode access

5

10

The configuration registers block examines the CPU access type (cpu_acode signal) and determines if the access is allowed to that particular register, based on configured user access registers. If an access is not allowed the block will issue a bus error by asserting the tim_cpu_berr signal.

The timers block is fully accessible in supervisor data mode, all registers can written to and read from. In user mode access is denied to all registers in the block except for the generic timer configuration registers that are granted user data access. User data access for a generic timer is granted by setting corresponding bit in the *GenCntUserModeEnable* register. This can only be changed in supervisor data mode. If a particular timer is granted user data access then all registers for configuring that timer will be accessible. For example if timer 0 is granted user data access the *GenCntStartValue[0]*, *GenCntUnitSel[0]*, *GenCntAuto[0]*, *GenCntEnable[0]* and *GenCntValue[0]* registers can all be written to and read from without any restriction.

Attempts to access a user data mode disabled timer configuration register will result in a bus error.

Table 93 details the access modes allowed for registers in the TIM block. In supervisor data mode all registers are accessable. All forbidden accesses will result in a bus error (tim_cpu_berr asserted).

Table 93. TIM supervisor and user access modes

5

Register	Registers	Access Permission
Address

16 Clocking, Power and Reset (CPR)

The CPR block provides all of the clock, power enable and reset signals to the SoPEC device.

16.1 POWERDOWN MODES

The CPR block is capable of powering down certain sections of the SoPEC device. When a section is powered down (i.e. put in sleep mode) no state is retained(except the PSS storage), the CPU must re-initialize the section before it can be used again.

For the purpose of powerdown the SoPEC device is divided into sections:

Table 94. Powerdown sectioning

Section	Block
Print Engine Pipeline	PCU
SubSystem (Section 0)	
	CDU
	CFU
	LBD
	SFU
	TE
	TFU
	HCU
	DNC
	DWU
	LLU
	PHI
CPU-DRAM (Section 1)	DRAM
	CPU/MMU
	DIU
	TIM
	ROM
	LSS
	PSS
	ICU
ISI Subsystem (Section 2)	ISI (SCB)
	DMA Ctrl (SCB)
	GPIO
USB Subsystem (Section 3)	USB (SCB)

Note that the CPR block is not located in any section. All configuration registers in the CPR block are clocked by an ungateable clock and have special reset conditions.

16.1.1 Sleep mode

5

10

Each section can be put into sleep mode by setting the corresponding bit in the *SleepModeEnable* register. To re-enable the section the sleep mode bit needs to be cleared and then the section should be reset by writing to the relevant bit in the *ResetSection* register. Each block within the section should then be re-configured by the CPU.

If the CPU system (section 1) is put into sleep mode, the SoPEC device will remain in sleep mode until a system level reset is initiated from the reset pin, or a wakeup reset by the SCB block as a result of activity on either the USB or ISI bus. The watchdog timer cannot reset the device as it is in section 1 also, and will be in sleep mode.

If the CPU and ISI subsystem are in sleep mode only a reset from the USB or a hardware reset will re-activate the SoPEC device.

If all sections are put into sleep mode, then only a system level reset initiated by the reset pin will re-activate the SoPEC device.

Like all software resets in SoPEC the *ResetSection* register is active-low i.e. a 0 should be written to each bit position requiring a reset. The *ResetSection* register is self-reseting.

5 16.1.2 Sleep Mode powerdown procedure

When powering down a section, the section may retain it's current state (although not gauranteed to). It is possible when powering back up a section that inconsistancies between interface state machines could cause incorrect operation. In order to prevent such condition from happening, all blocks in a section must be disabled before powering down. This will ensure that blocks are

10 restored in a benign state when powered back up.

In the case of PEP section units setting the *Go* bit to zero will disable the block. The DRAM subsystem can be effectively disabled by setting the *RotationSync* bit to zero, and the SCB system disabled by setting the *DMAAccessEn* bits to zero turning off the DMA access to DRAM. Other CPU subsystem blocks without any DRAM access do not need to be disabled.

15 16.2 RESET SOURCE

25

30

35

The SoPEC device can be reset by a number of sources. When a reset from an internal source is initiated the reset source register (*ResetSrc*) stores the reset source value. This register can then be used by the CPU to determine the type of boot sequence required.

16.3 CLOCK RELATIONSHIP

The crystal oscillator excites a 32MHz crystal through the xtalin and xtalout pins. The 32MHz output is used by the PLL to derive the master VCO frequency of 960MHz. The master clock is then divided to produce 320MHz clock (*clk320*), 160MHz clock (*clk160*) and 48MHz (*clk48*) clock sources.

The phase relationship of each clock from the PLL will be defined. The relationship of internal clocks *clk320*, *clk48* and *clk160* to *xtalin* will be undefined.

At the output of the clock block, the skew between each *pclk* domain (*pclk_section[2:0]* and *jclk*) should be within skew tolerances of their respective domains (defined as less than the hold time of a D-type flip flop).

The skew between *doclk* and *pclk* should also be less than the skew tolerances of their respective domains.

The *usbclk* is derived from the PLL output and has no relationship with the other clocks in the system and is considered asynchronous.

16.4 PLL CONTROL

The PLL in SoPEC can be adjusted by programming the *PLLRangeA*, *PLLRangeB*, *PLLTunebits* and *PLLMult* registers. If these registers are changed by the CPU the values are not updated until the *PLLUpdate* register is written to. Writing to the *PLLUpdate* register triggers the PLL control state machine to update the PLL configuration in a safe way. When an update is active (as indicated by *PLLUpdate* register) the CPU must not change any of the configuration registers, doing so could cause the PLL to lose lock indefintely, requiring a hardware reset to recover. Configuring the PLL

registers in an inconsistent way can also cause the PLL to lose lock, care must taken to keep the PLL configuration within specified parameters.

The VCO frequency of the PLL is calculated by the number of divider in the feedback path. PLL output A is used as the feedback source.

5 VCOfreq = REFCLK x PLLMult x PLLRangeA x External divider

VCOfreq = $32 \times 3 \times 10 \times 1 = 960 \text{ Mhz}$.

In the default PLL setup, *PLLMult* is set to 3, *PLLRangeA* is set to 3 which corresponds to a divide by 10, *PLLRangeB* is set to 5 which corresponds to a divide by 3.

PLLouta = VCOfreq / PLLRangeA = 960Mhz / 10 = 96 Mhz

10 PLLoutb = VCOfreq / PLLRangeB = 960Mhz / 3 = 320 Mhz

See [16] for complete PLL setup parameters.

16.5 IMPLEMENTATION

16.5.1 Definitions of I/O

Table 95. CPR I/O definition

15

Port name	Pins	1/0	Description	
Clocks and Resets				
Xtalin	1	ln	Crystal input, direct from IO pin.	
Xtalout	1	Inout	Crystal output, direct to IO pin.	
pclk_section[3:0]	4	Out	System clocks for each section	
Doclk	1	Out	Data out clock (2x pclk) for the PHI block	
Jclk	1	Out	Gated version of system clock used to clock the	
			JPEG decoder core in the CDU	
Usbcik	1	Out	USB clock, nominally at 48 Mhz	
jclk_enable	1	ln	Gating signal for jclk. When 1 jclk is enabled	
reset_n	1	ln	Reset signal from the reset_n pin	
usb_cpr_reset_n	1	ln	Reset signal from the USB block	
isi_cpr_reset_n	1	In	Reset signal from the ISI block	
tim_cpr_reset_n	1	In	Reset signal from watch dog timer.	
gpio_cpr_wakeup	1	ln	SoPEC wake up from the GPIO, active high.	
prst_n_section[3:0]	4	Out	System resets for each section, synchronous	
			active low	
dorst_n	1	Out	Reset for PHI block, synchronous to doclk	
jrst_n	1	Out	Reset for JPEG decoder core in CDU block,	
			synchronous to jclk	
usbrst_n	1	Out	Reset for the USB block, synchronous to usbclk	
CPU interface		-		
cpu_adr[5:2]	3	In	CPU address bus. Only 4 bits are required to	
			decode the address space for the CPR block	

cpu_dataout[31:0]	32	ln	Shared write data bus from the CPU	
cpr_cpu_data[31:0]	32	Out	Read data bus to the CPU	
cpu_rwn	1	In	Common read/not-write signal from the CPU	
cpu_cpr_sel	1	ln	Block select from the CPU. When cpu_cpr_sel is	
			high both <i>cpu_adr</i> and <i>cpu_dataout</i> are valid	
cpr_cpu_rdy	1	Out	Ready signal to the CPU. When cpr_cpu_rdy is	
			high it indicates the last cycle of the access. For a	
			write cycle this means cpu_dataout has been	
			registered by the block and for a read cycle this	
			means the data on <i>cpr_cpu_data</i> is valid.	
cpr_cpu_berr	1	Out	Bus error signal to the CPU indicating an invalid	
			access.	
cpu_acode[1:0]	2	In	CPU Access Code signals. These decode as

16.5.2 Configuration registers

5

10

The configuration registers in the CPR are programmed via the CPU interface. Refer to section 11.4 on page 69 for a description of the protocol and timing diagrams for reading and writing registers in the CPR. Note that since addresses in SoPEC are byte aligned and the CPU only supports 32-bit register reads and writes, the lower 2 bits of the CPU address bus are not required to decode the address space for the CPR. When reading a register that is less than 32 bits wide zeros should be returned on the upper unused bit(s) of *cpr_pcu_data*. Table 96 lists the configuration registers in the CPR block.

The CPR block will only allow supervisor data mode accesses (i.e. cpu_acode[1:0] = SUPERVISOR_DATA). All other accesses will result in cpr_cpu_berr being asserted.

Table 96. CPR Register Map

Address CPR_base +	Register	#bits	Reset	Description
0x00	SleepModeEnable	4		Sleep Mode enable, when high a section of logic is put into powerdown. Bit 0 - Controls section 0 Bit 1 - Controls section 1 Bit 2 - Controls section 2

		1	1	Bit 3 - Controls section 3
			1	Note that the SleepModeEnable register
				has special reset conditions. See
				Section 16.5.6 for details
0.04	D+0	-	İ	
0x04	ResetSrc	5	į.	Reset Source register, indicating the
				source of the last reset (or wake-up)
			1	Bit 0 - External Reset
				Bit 1 - USB wakeup reset
			1	Bit 2 - ISI wakeup reset
				Bit 3 - Watchdog timer reset
				Bit 4 - GPIO wake-up
				(Read Only Register)
0x08	ResetSection	4	0xF	Active-low synchronous reset for each
				section, self-resetting.
				Bit 0 - Controls section 0
				Bit 1 - Controls section 1
				Bit 2 - Controls section 2
:				Bit 3 - Controls section 3
0x0C	DebugSelect[5:2]	4	0x0	Debug address select. Indicates the
				address of the register to report on the
				cpr_cpu_data bus when it is not
				otherwise being used.
PLL Control		<u> </u>	<u> </u>	
0x10	PLLTuneBits	10	0x3BC	PLL tuning bits
0x14	PLLRangeA	4	0x3	PLLOUT A frequency selector (defaults
			1	to 60Mhz to 125Mhz)
0x18	PLLRangeB	3	0x5	PLLOUT B frequency selector (defaults
				to 200Mhz to 400Mhz)
0x1C	PLLMultiplier	5	0x03	PLL multiplier selector, defaults to
			:	refclk x 3
0x20	PLLUpdate	1	0x0	PLL update control. A write (of any
				value) to this register will cause the
				PLL to lose lock for ~100us. Reading
				the register indicates the status of the
				update.
				0 - PLL update complete
	,			1 - PLL update active
				No writes to
				PLLTuneBits,PLLRangeA,PLL-
L				

	RangeB,PLLMultiplier or PLLUpdate
	are allowed while the PLL update is
	active.

a. Reset value depends on reset source. External reset shown.

16.5.3 CPR Sub-block partition

16.5.4 reset_n deglitch

The external reset_n signal is deglitched for about 1µs. reset_n must maintain a state for 1us second before the state is passed into the rest of the device. All deglitch logic is clocked on bufrefclk.

16.5.5 Sync reset

The reset synchronizer retimes an asynchronous reset signal to the clock domain that it resets. The circuit prevents the inactive edge of reset occurring when the clock is rising

10 16.5.6 Reset generator logic

The reset generator logic is used to determine which clock domains should be reset, based on configured reset values (reset_section_n), the external reset (reset_n), watchdog timer reset (tim_cpr_reset_n), the USB reset (usb_cpr_reset_n), the GPIO wakeup control (gpio_cpr_wakeup) and the ISI reset (isi_cpr_reset_n). The reset direct from the IO pin (reset_n) is synchronized and de-glitched before feeding the reset logic.

All resets are lengthened to at least 16 *pclk* cycles, regardless of the duration of the input reset. The clock for a particular section must be running for the reset to have an effect. The clocks to each section can be enabled/disabled using the *SleepModeEnable* register.

Resets from the ISI or USB block reset everything except its own section (section 2 or 3).

20

15

Table 97. Reset domains

Reset signal	Domain			
reset_dom[0]	Section 0 pclk domain (PEP)			
reset_dom[1]	Section 1 pclk domain (CPU)			
reset_dom[2]	Section 2 pclk domain (ISI)			
reset_dom[3]	Section 3 usbclk/pclk domain			
	(USB)			
reset_dom[4]	doclk domain			
reset_dom[5]	jclk domain			

The logic is given by

25

```
= 0x00 // reset everything except
                    reset_dom[5:0]
                 CPR config
                    reset src[4:0]
                                        = 0x08
                    cfg_reset_n
                                                    // CPR config stays the same

                      reset dom[1] = 0
                                                      // pclk section 1 domain
40
                    if (reset_section_n[2] == 0) then
                      reset_dom[2] = 0
                                                        // pclk section 2 domain
                  (ISI)
                    if (reset_section_n[3] == 0) then
                      reset_dom[3] = 0
                                                      // USB domain
45
```

The sleep logic is used to generate gating signals for each of SoPECs clock domains. The gate enable (*gate_dom*) is generated based on the configured *sleep_mode_en* and the internally generated *jclk_enable* signal.

The logic is given by

```
5
                   // clock gating for sleep modes
                   gate dom[5:0] = 0x0
                                                       // default to all clocks
                 on
                   if (sleep_mode_en[0] == 1) then  // section 0 sleep
                     gate dom[0] = 1
                                                     // pclk section 0
10
                     gate dom[4] = 1
                                                     // doclk domain
                     gate dom[5] = 1
                                                    // jclk domain
                   if (sleep_mode_en[1] == 1) then
                                                     // section 1 sleep
                     gate_dom[1] = 1
                                                     // pclk section 1
                   if (sleep mode en[2] == 1) then // section 2 sleep
15
                     gate_dom[2] = 1
                                                     // pclk section 2
                   if (sleep_mode_en[3] == 1) then  // section 3 sleep
                     gate_dom[3] = 1
                                                     // usb section 3
                   // the jclk can be turned off by CDU signal
                   if (jclk enable == 0) then
20
                     gate_dom[5] = 1
```

The clock gating and sleep logic is clocked with the *master_pclk* clock which is not gated by this logic, but is synchronous to other *pclk_section* and *jclk* domains.

Once a section is in sleep mode it cannot generate a reset to restart the device. For example if section 1 is in sleep mode then the watchdog timer is effectively disabled and cannot trigger a reset.

25 16.5.8 Clock gate logic

30

The clock gate logic is used to safely gate clocks without generating any glitches on the gated clock. When the enable is high the clock is active otherwise the clock is gated.

16.5.9 Clock generator Logic

The clock generator block contains the PLL, crystal oscillator, clock dividers and associated control logic. The PLL VCO frequency is at 960MHz locked to a 32 MHz *refclk* generated by the crystal oscillator. In test mode the *xtalin* signal can be driven directly by the test clock generator, the test clock will be reflected on the *refclk* signal to the PLL.

16.5.9.1 Clock divider A

The clock divider A block generates the 48MHz clock from the input 96MHz clock (pllouta)

35 generated by the PLL. The divider is enabled only when the PLL has acquired lock.

16.5.9.2 Clock divider B

The clock divider B block generates the 160MHz clocks from the input 320MHz clock (*plloutb*) generated by the PLL. The divider is enabled only when the PLL has acquired lock.

16.5.9.3 PLL control state machine

The PLL will go out of lock whenever *pll_reset* goes high (the PLL reset is the only active high reset in the device) or if the configuration bits *pll_rangea*, *pll_rangeb*, *pll_mult*, *pll_tune* are changed. The

PLL control state machine ensures that the rest of the device is protected from glitching clocks while the PLL is being reset or it's configuration is being changed.

In the case of a hardware reset (the reset is deglitched), the state machine first disables the output clocks (via the *clk_gate* signal), it then holds the PLL in reset while its configuration bits are reset to default values. The state machine then releases the PLL reset and waits approx. 100us to allow the PLL to regain lock. Once the lock time has elapsed the state machine re-enables the output clocks and resets the remainder of the device via the *reset_dg_n* signal.

When the CPU changes any of the configuration registers it must write to the PLLupdate register to allow the state machine to update the PLL to the new configuration setup. If a PLLUpdate is

- detected the state machine first gates the output clocks. It then holds the PLL in reset while the PLL configuration registers are updated. Once updated the PLL reset is released and the state machine waits approx 100us for the PLL to regain lock before re-enabling the output clocks. Any write to the PLLUpdate register will cause the state machine to perform the update operation regardless of whether the configuration values changed or not.
- All logic in the clock generator is clocked on *bufrefclk* which is always an active clock regardless of the state of the PLL.

17 ROM Block

5

20

25

30

35

40

17.1 OVERVIEW

The ROM block interfaces to the CPU bus and contains the SoPEC boot code. The ROM block consists of the CPU bus interface, the ROM macro and the ChipID macro. The current ROM size is 16 KBytes implemented as a 4096 x32 macro. Access to the ROM is not cached because the CPU enjoys fast (no more than one cycle slower than a cache access), unarbitrated access to the ROM. Each SoPEC device is required to have a unique ChipID which is set by blowing fuses at manufacture. IBM's 300mm ECID macro and a custom 112-bit ECID macro are used to implement the ChipID offering 224-bits of laser fuses. The exact number of fuse bits to be used for the ChipID will be determined later but all bits are made available to the CPU. The ECID macros allows all 224 bits to be read out in parallel and the ROM block will make all 224 bits available in the FuseChipID[N] registers which are readable by the CPU in supervisor mode only.

17.2 BOOT OPERATION

The are two boot scenarios for the SoPEC device namely after power-on and after being awoken from sleep mode. When the device is in sleep mode it is hoped that power will actually be removed from the DRAM, CPU and most other peripherals and so the program code will need to be freshly downloaded each time the device wakes up from sleep mode. In order to reduce the wakeup boot time (and hence the perceived print latency) certain data items are stored in the PSS block (see section 18). These data items include the SHA-1 hash digest expected for the program(s) to be downloaded, the master/slave SoPEC id and some configuration parameters. All of these data items are stored in the PSS by the CPU prior to entering sleep mode. The SHA-1 value stored in the PSS is calculated by the CPU by decrypting the signature of the downloaded program using the appropriate public key stored in ROM. This compute intensive decryption only needs to take place once as part of the power-on boot sequence - subsequent wakeup boot sequences will simply use

the resulting SHA-1 digest stored in the PSS. Note that the digest only needs to be stored in the PSS before entering sleep mode and the PSS can be used for temporary storage of any data at all other times.

The CPU is expected to be in supervisor mode for the entire boot sequence described by the pseudocode below. Note that the boot sequence has not been finalised but is expected to be close to the following:

5

```
if (ResetSrc == 1) then
                                             // Reset was a power-on reset
                     configure sopec // need to configure peris (USB, ISI,
10
                 DMA, ICU etc.)
                   // Otherwise reset was a wakeup reset so peris etc. were
                 already configured
                   PAUSE: wait until IrqSemaphore != 0 // i.e. wait until an
                 interrupt has been serviced
15
                   if (IrqSemaphore == DMAChan0Msg) then
                     parse msg(DMAChan0MsgPtr) // this routine will parse the
                 message and take any
                                          // necessary action e.g. programming
                 the DMAChannell registers
20
                   elsif (IrqSemaphore == DMAChan1Msg) then
                                                               // program has
                 been downloaded
                     CalculatedHash = gen shal(ProgramLocn, ProgramSize)
                     if (ResetSrc == 1) then
                       ExpectedHash = sig_decrypt(ProgramSig,public_key)
25
                     else

                     if (ExpectedHash == CalculatedHash) then
                        jmp(PrgramLocn) // transfer control to the downloaded
                 program
30
                     else
                        send host msg("Program Authentication Failed")
                       goto PAUSE:
                     elsif (IrqSemaphore == timeout) then
                                                               // nothing has
                 happened
35
                        if (ResetSrc == 1)
                        sleep_mode() // put SoPEC into sleep mode to be woken
                 up by USB/ISI activity
                        else // we were woken up but nothing happened
40
                          reset sopec (PowerOnReset)
                     else
                       goto PAUSE
```

The boot code places no restrictions on the activity of any programs downloaded and authenticated by it other than those imposed by the configuration of the MMU i.e. the principal function of the boot

code is to authenticate that any programs downloaded by it are from a trusted source. It is the responsibility of the downloaded program to ensure that any code it downloads is also authenticated and that the system remains secure. The downloaded program code is also responsible for setting the SoPEC ISIId (see section 12.5 for a description of the ISIId) in a multi -SoPEC system. See the "SoPEC Security Overview" document [9] for more details of the SoPEC security features.

17.3 IMPLEMENTATION

5

17.3.1 Definitions of I/O

Table 98. ROM Block I/O

Port name	Pins	1/0	Description		
Clocks and Resets					
prst_n	1	ln	Global reset. Synchronous to pclk, active low.		
Pclk	1	ln	Global clock		
CPU Interface					
cpu_adr[14:2]	13	In	CPU address bus. Only 13 bits are required to		
			decode the address space for this block.		
rom_cpu_data[31:	32	Out	Read data bus to the CPU		
0]					
cpu_rwn	1	In	Common read/not-write signal from the CPU		
cpu_acode[1:0]	2	ln	CPU Access Code signals. These decode as		
			follows:		
			00 - User program access		
			01 - User data access		
			10 - Supervisor program access		
			11 - Supervisor data access		
cpu_rom_sel	1	ln	Block select from the CPU. When cpu_rom_sel		
1			is high <i>cpu_adr</i> is valid		
rom_cpu_rdy	1	Out	Ready signal to the CPU. When rom_cpu_rdy is		
			high it indicates the last cycle of the access. For		
			a read cycle this means the data on		
			rom_cpu_data is valid.		
rom_cpu_berr	om_cpu_berr 1 Out		ROM bus error signal to the CPU indicating an		
			invalid access.		

10 17.3.2 Configuration registers

15

The ROM block will only allow read accesses to the *FuseChipID* registers and the ROM with supervisor data space permissions (i.e. *cpu_acode[1:0]* = 11). Write accesses with supervisor data space permissions

will have no effect. All other accesses with will result in *rom_cpu_berr* being asserted. The CPU subsystem bus slave interface is described in more detail in section 9.4.3.

Table 99. ROM Block Register Map

Address ROM_base +	Register	#bits	Reset	Description
0x4000	FuseChipID0	32	n/a	Value of corresponding fuse bits 31 to 0
				of the IBM 112-bit ECID macro. (Read
				only)
0x4004	FuseChipID1	32	n/a	Value of corresponding fuse bits 63 to 32
				of the IBM 112-bit ECID macro. (Read
				only)
0x4008	FuseChipID2	32	n/a	Value of corresponding fuse bits 95 to 64
				of the IBM 112-bit ECID macro. (Read
				only)
0x400C	FuseChipID3	16.	n/a	Value of corresponding fuse bits 111 to
				96 of the IBM 112-bit ECID macro. (Read
			1	only)
0x4010	FuseChipID4	32	n/a	Value of corresponding fuse bits 31 to 0
				of the Custom 112-bit ECID macro. (Read
				only)
0x4014	FuseChipID5	32	n/a	Value of corresponding fuse bits 63 to 32
				of the Custom 112-bit ECID macro. (Read
				only)
0x4018	FuseChipID6	32	n/a	Value of corresponding fuse bits 95 to 64
				of the Custom 112-bit ECID macro. (Read
				only) .
0x401C	FuseChipID7	16	n/a	Value of corresponding fuse bits 111 to
				96 of the Custom 112-bit ECID macro.
				(Read only)

17.3.3 Sub-Block Partition

IBM offer two variants of their ROM macros; A high performance version (ROMHD) and a low power version (ROMLD). It is likely that the low power version will be used unless some implementation issue requires the high performance version. Both versions offer the same bit density. The sub-block partition diagram below does not include the clocking and test signals for the ROM or ECID macros. The CPU subsystem bus interface is described in more detail in section 11.4.3.

17.3.4 Table 100. ROM Block internal signals

5

Internal Signals		
rom_adr[11:0]	12	ROM address bus
rom_sel	1	Select signal to the ROM macro instructing it to access the location at <i>rom_adr</i>
rom_oe	1	Output enable signal to the ROM block
rom_data[31:0]	32	Data bus from the ROM macro to the CPU bus interface
rom_dvalid	1	Signal from the ROM macro indicating that the data on rom_data is valid for the address on rom_adr
fuse_data[31:0]	32	Data from the FuseChipID[N] register addressed by fuse_reg_adr
fuse_reg_adr[2:0]	3	Indicates which of the FuseChipID registers is being addressed

Sub-block signal definition

18 Power Safe Storage (PSS) Block

18.1 OVERVIEW

5

25

The PSS block provides 128 bytes of storage space that will maintain its state when the rest of the SoPEC device is in sleep mode. The PSS is expected to be used primarily for the storage of decrypted signatures associated with downloaded programmed code but it can also be used to store any information that needs to survive sleep mode (e.g. configuration details). Note that the signature digest only needs to be stored in the PSS before entering sleep mode and the PSS can be used for temporary storage of any data at all other times.

Prior to entering sleep mode the CPU should store all of the information it will need on exiting sleep mode in the PSS. On emerging from sleep mode the boot code in ROM will read the *ResetSrc* register in the CPR block to determine which reset source caused the wakeup. The reset source information indicates whether or not the PSS contains valid stored data, and the PSS data determines the type of boot sequence to execute. If for any reason a full power-on boot sequence should be performed (e.g. the printer driver has been updated) then this is simply achieved by initiating a full software reset.

Note that a reset or a powerdown (powerdown is implemented by clock gating) of the PSS block will not clear the contents of the 128 bytes of storage. If clearing of the PSS storage is required, then the CPU must write to each location individually.

20 18.2 IMPLEMENTATION

The storage area of the PSS block will be implemented as a 128-byte register array. The array is located from PSS_base through to PSS_base+0x7F in the address map. The PSS block will only allow read or write accesses with supervisor data space permissions (i.e. $cpu_acode[1:0] = 11$). All other accesses will result in pss_cpu_berr being asserted. The CPU subsystem bus slave interface is described in more detail in section 11.4.3.

18.2.1 Definitions of I/O

Table 101. PSS Block I/O

Port name	Pins	1/0	Description	
Clocks and Resets	1	·		
prst_n	1	ln	Global reset. Synchronous to pclk, active low.	
Pclk	1	In	Global clock	
CPU Interface		· 		
cpu_adr[6:2]	5	ln	CPU address bus. Only 5 bits are required to	
			decode the address space for this block.	
cpu_dataout[31:0]	32	ln	Shared write data bus from the CPU	
pss_cpu_data[31:0]	32	Out	Read data bus to the CPU	
cpus_rwn	1	ln	Common read/not-write signal from the CPU	
cpu_acode[1:0]	2	In	CPU Access Code signals. These decode as	
			follows:	
			00 - User program access	
			01 - User data access	
:			10 - Supervisor program access	
			11 - Supervisor data access	
cpu_pss_sel	1	In	Block select from the CPU. When cpu_pss_sel is	
•			high both <i>cpu_adr</i> and <i>cpu_dataout</i> are valid	
pss_cpu_rdy	1	Out	Ready signal to the CPU. When pss_cpu_rdy is high	
			it indicates the last cycle of the access. For a read	
			cycle this means the data on <i>pss_cpu_data</i> is valid.	
pss_cpu_berr	1	Out	PSS bus error signal to the CPU indicating an	
			invalid access.	

19 Low Speed Serial Interface (LSS)

19.1 OVERVIEW

5

10

15

The Low Speed Serial Interface (LSS) provides a mechanism for the internal SoPEC CPU to communicate with external QA chips via two independent LSS buses. The LSS communicates through the GPIO block to the QA chips. This allows the QA chip pins to be reused in multi-SoPEC environments. The LSS Master system-level interface is illustrated in Figure 75. Note that multiple QA chips are allowed on each LSS bus.

19.2 QA COMMUNICATION

The SoPEC data interface to the QA Chips is a low speed, 2 pin, synchronous serial bus. Data is transferred to the QA chips via the *Iss_data* pin synchronously with the *Iss_clk* pin. When the *Iss_clk* is high the data on *Iss_data* is deemed to be valid. Only the LSS master in SoPEC can drive the *Iss_clk* pin, this pin is an input only to the QA chips. The LSS block must be able to interface with an open-collector pull-up bus. This means that when the LSS block should transmit a logical zero it will drive 0 on the bus, but when it should transmit a logical 1 it will leave high-impedance on the bus (i.e. it doesn't drive the bus). If all the agents on the LSS bus adhere to this protocol then there will be no issues with bus contention.

The LSS block controls all communication to and from the QA chips. The LSS block is the bus master in all cases. The LSS block interprets a command register set by the SoPEC CPU, initiates transactions to the QA chip in question and optionally accepts return data. Any return information is presented through the configuration registers to the SoPEC CPU. The LSS block indicates to the CPU the completion of a command or the occurrence of an error via an interrupt. The LSS protocol can be used to communicate with other LSS slave devices (other than QA chips). However should a LSS slave device hold the clock low (for whatever reason), it will be in violation of the LSS protocol and is not supported. The LSS clock is only ever driven by the LSS master.

10 19.2.1 Start and stop conditions

5

15

20

25

30

35

40

All transmissions on the LSS bus are initiated by the LSS master issuing a START condition and terminated by the LSS master issuing a STOP condition. START and STOP conditions are always generated by the LSS master. As illustrated in Figure 76, a START condition corresponds to a high to low transition on *Iss_data* while *Iss_clk* is high. A STOP condition corresponds to a low to high transition on *Iss_data* while *Iss_clk* is high.

19.2.2 Data transfer

Data is transferred on the LSS bus via a byte orientated protocol. Bytes are transmitted serially. Each byte is sent most significant bit (MSB) first through to least significant bit (LSB) last. One clock pulse is generated for each data bit transferred. Each byte must be followed by an acknowledge bit.

The data on the *Iss_data* must be stable during the HIGH period of the *Iss_clk* clock. Data may only change when *Iss_clk* is low. A transmitter outputs data after the falling edge of *Iss_clk* and a receiver inputs the data at the rising edge of *Iss_clk*. This data is only considered as a valid data bit at the next *Iss_clk* falling edge provided a START or STOP is not detected in the period before the next *Iss_clk* falling edge. All clock pulses are generated by the LSS block. The transmitter releases the *Iss_data* line (high) during the acknowledge clock pulse (ninth clock pulse). The receiver must pull down the *Iss_data* line during the acknowledge clock pulse so that it remains stable low during the HIGH period of this clock pulse.

Data transfers follow the format shown in Figure 77. The first byte sent by the LSS master after a START condition is a primary id byte, where bits 7-2 form a 6-bit primary id (0 is a global id and will address all QA Chips on a particular LSS bus), bit 1 is an even parity bit for the primary id, and bit 0 forms the read/ write sense. Bit 0 is high if the following command is a read to the primary id given or low for a write command to that id. An acknowledge is generated by the QA chip(s) corresponding to the given id (if such a chip exists) by driving the *Iss_data* line low synchronous with the LSS master generated ninth *Iss_clk*.

19.2.3 Write procedure

The protocol for a write access to a QA Chip over the LSS bus is illustrated in Figure 79 below. The LSS master in SoPEC initiates the transaction by generating a START condition on the LSS bus. It then transmits the primary id byte with a 0 in bit 0 to indicate that the following command is a write to the primary id. An acknowledge is generated by the QA chip corresponding to the given

primary id. The LSS master will clock out M data bytes with the slave QA Chip acknowledging each successful byte written. Once the slave QA chip has acknowledged the Mth data byte the LSS master issues a STOP condition to complete the transfer. The QA chip gathers the M data bytes together and interprets them as a command. See QA Chip Interface Specification for more details on the format of the commands used to communicate with the QA chip[8]. Note that the QA chip is free to not acknowledge any byte transmitted. The LSS master should respond by issuing an interrupt to the CPU to indicate this error. The CPU should then generate a STOP condition on the LSS bus to gracefully complete the transaction on the LSS bus.

19.2.4 Read procedure

5

20

The LSS master in SoPEC initiates the transaction by generating a START condition on the LSS bus. It then transmits the primary id byte with a 1 in bit 0 to indicate that the following command is a read to the primary id. An acknowledge is generated by the QA chip corresponding to the given primary id. The LSS master releases the *Iss_data* bus and proceeds to clock the expected number of bytes from the QA chip with the LSS master acknowledging each successful byte read.
The last expected byte is not acknowledged by the LSS master. It then completes the transaction by generating a STOP condition on the LSS bus. See QA Chip Interface Specification for more details on the format of the commands used to communicate with the QA chip[8].

19.3 IMPLEMENTATION

A block diagram of the LSS master is given in Figure 80. It consists of a block of configuration registers that are programmed by the CPU and two identical LSS master units that generate the signalling protocols on the two LSS buses as well as interrupts to the CPU. The CPU initiates and terminates transactions on the LSS buses by writing an appropriate command to the command register, writes bytes to be transmitted to a buffer and reads bytes received from a buffer, and checks the sources of interrupts by reading status registers.

25 19.3.1 Definitions of IO

Table 102. LSS IO pins definitions

Port name	Pins	1/0	Description	
Clocks and Resets				
Pclk	1	ln	System Clock	
prst_n	1	In	System reset, synchronous active low	
CPU Interface		L		
cpu_rwn	1	ln	Common read/not-write signal from the CPU	
cpu_adr[6:2]	5	ln	CPU address bus. Only 5 bits are required to decode the address space for this block	
cpu_dataout[31:0]	32	ln	Shared write data bus from the CPU	
cpu_acode[1:0]	2	In .	CPU access code signals. cpu_acode[0] - Program (0) / Data (1) access cpu_acode[1] - User (0) / Supervisor (1) access	

cpu_lss_sel	1	In	Block select from the CPU. When cpu_lss_sel is
			high both <i>cpu_adr</i> and <i>cpu_dataout</i> are valid
lss_cpu_rdy	1	Out	Ready signal to the CPU. When <i>lss_cpu_rdy</i> is high
			it indicates the last cycle of the access. For a write
			cycle this means <i>cpu_dataout</i> has been registered
			by the LSS block and for a read cycle this means
			the data on <i>lss_cpu_data</i> is valid.
lss_cpu_berr	1	Out	LSS bus error signal to the CPU.
lss_cpu_data[31:0]	32	Out	Read data bus to the CPU
lss_cpu_debug_valid	1	Out	Active high. Indicates the presence of valid debug
			data on <i>lss_cpu_data.</i>
GPIO for LSS buses		· · · · · · · · · · · · · · · · · · ·	
lss_gpio_dout[1:0]	2	Out	LSS bus data output
			Bit 0 - LSS bus 0
			Bit 1 - LSS bus 1
gpio_lss_din[1:0]	2	ln	LSS bus data input
			Bit 0 - LSS bus 0
			Bit 1 - LSS bus 1
lss_gpio_e[1:0]	2	Out	LSS bus data output enable, active high
			Bit 0 - LSS bus 0
			Bit 1 - LSS bus 1
lss_gpio_clk[1:0]	2	Out	LSS bus clock output
	1		Bit 0 - LSS bus 0
			Bit 1 - LSS bus 1
ICU interface			
lss_icu_irq[1:0]	2	Out	LSS interrupt requests
			Bit 0 - interrupt associated with LSS bus 0
			Bit 1 - interrupt associated with LSS bus 1

19.3.2 Configuration registers

5

The configuration registers in the LSS block are programmed via the CPU interface. Refer to section 11.4 on page 69 for the description of the protocol and timing diagrams for reading and writing registers in the LSS block. Note that since addresses in SoPEC are byte aligned and the CPU only supports 32-bit register reads and writes, the lower 2 bits of the CPU address bus are not required to decode the address space for the LSS block. Table 103 lists the configuration registers in the LSS block. When reading a register that is less than 32 bits wide zeros should be returned on the upper unused bit(s) of *Iss_cpu_data*.

The input *cpu_acode* signal indicates whether the current CPU access is supervisor, user,

program or data. The configuration registers in the LSS block can only be read or written by a
supervisor data access, i.e. when *cpu_acode* equals b11. If the current access is a supervisor
data access then the LSS responds by asserting *lss_cpu_rdy* for a single clock cycle.

If the current access is anything other than a supervisor data access, then the LSS generates a bus error by asserting *Iss_cpu_berr* for a single clock cycle instead of *Iss_cpu_rdy* as shown in section 11.4 on page 69. A write access will be ignored, and a read access will return zero.

Table 103. LSS Control Registers

5

Address (LSS_base +)	Register	#bits	Reset	Description
Control registe	rs			
0x00	Reset	1	0x1	A write to this register causes a reset of the LSS.
0x04	LssClockHighLow- Duration	16	0x00C8	Lss_clk has a 50:50 duty cycle, this register defines the period of lss_clk by means of specifying the duration (in pclk cycles) that lss_clk is low (or high). The reset value specifies transmission over the LSS bus at a nominal rate of 400kHz, corresponding to a low (or high) duration of 200 pclk (160Mhz) cycles. Register should not be set to values less than 8.
0x08	LssClocktoDataHo ld	6	0x3	Specifies the number of <i>pclk</i> cycles that Data must remain valid for after the falling edge of <i>lss_clk</i> . Minimum value is 3 cycles, and must to programmed to be less than LssClockHighLowDuration.
LSS bus 0 reg	isters	L		· · · · · · · · · · · · · · · · · · ·
0x10	Lss0IntStatus	3	0x0	LSS bus 0 interrupt status registers Bit 0 - command completed successfully Bit 1 - error during processing of command, not -acknowledge received after transmission of primary id byte on LSS bus 0 Bit 2 - error during processing of command, not -acknowledge received after transmission of data byte on LSS bus 0 All the bits in Lss0IntStatus are cleared when the Lss0Cmd register gets written to.

				(Read only register)
0x14	Lss0CurrentState	4	0x0	Gives the current state of the LSS bus 0
				state machine. (Read only register).
				(Encoding will be specified upon state
				machine implementation)
0x18	Lss0Cmd	21	0x00	Command register defining sequence of
			_0000	events to perform on LSS bus 0 before
	,			interrupting CPU.
				A write to this register causes all the bits in
				the Lss0IntStatus register to be cleared as
				well as generating a <i>lss0_new_cmd</i> pulse.
0x1C - 0x2C	Lss0Buffer[4:0]	5x32	0x0000	LSS Data buffer. Should be filled with
			_0000	transmit data before transmit command, or
				read data bytes received after a valid read
				command.
LSS bus 1 reg	pisters			
0x30	Lss1IntStatus	3	0x0	LSS bus 1 interrupt status registers
				Bit 0 - command completed successfully
				Bit 1 - error during processing of command,
				not -acknowledge received after
				transmission
				of primary id byte on LSS bus 1
			-	Bit 2 - error during processing of command,
			İ	not -acknowledge received after
				transmission
				of data byte on LSS bus 1
				All the bits in Lss1IntStatus are cleared when
				the Lss1Cmd register gets written to.
				(Read only register)
0x34	Lss1CurrentState	4	0x0	Gives the current state of the LSS bus 1
				state machine. (Read only register)
				(Encoding will be specified upon state
				machine implementation)
0x38	Lss1Cmd	21	0x00_	Command register defining sequence of
			0000	events to perform on LSS bus 1 before
				interrupting CPU.
				A write to this register causes all the bits in
				the Lss1IntStatus register to be cleared as
1	ı	1	1	well as generating a <i>lss1_new_cmd</i> pulse.

0x3C - 0x4C	Lss1Buffer[4:0]	5x32	0x0000	LSS Data buffer. Should be filled with
			_0000	transmit data before transmit command, or
				read data bytes received after a valid read
				command.
Debug register	'S	•		
0×50	LssDebugSel[6:2]	5	0x00	Selects register for debug output. This value
				is used as the input to the register decode
				logic instead of cpu_adr[6:2] when the LSS
				block is not being accessed by the CPU, i.e.
				when <i>cpu_lss_sel</i> is 0.
				The output <i>lss_cpu_debug_valid</i> is asserted
				to indicate that the data on Iss_cpu_data is
				valid debug data. This data can be
				mutliplexed onto chip pins during debug
				mode.

19.3.2.1 LSS command registers

5

15

20

25

The LSS command registers define a sequence of events to perform on the respective LSS bus before issuing an interrupt to the CPU. There is a separate command register and interrupt for each LSS bus. The format of the command is given in Table 104. The CPU writes to the command register to initiate a sequence of events on an LSS bus. Once the sequence of events has completed or an error has occurred, an interrupt is sent back to the CPU. Some example commands are:

- a single START condition (Start = 1, IdByteEnable = 0, RdWrEnable = 0, Stop = 0)
- a single STOP condition (Start = 0, IdByteEnable = 0, RdWrEnable = 0, Stop = 1)
- a START condition followed by transmission of the id byte (Start = 1, IdByteEnable = 1, RdWrEnable = 0, Stop = 0, IdByte contains primary id byte)
 - a write transfer of 20 bytes from the data buffer (Start = 0, IdByteEnable = 0, RdWrEnable = 1, RdWrSense = 0, Stop = 0, TxRxByteCount = 20)
 - a read transfer of 8 bytes into the data buffer (Start = 0, IdByteEnable = 0, RdWrEnable = 1, RdWrSense = 1, ReadNack = 0, Stop = 0, TxRxByteCount = 8)
 - a complete read transaction of 16 bytes (Start = 1, IdByteEnable = 1, RdWrEnable = 1, RdWrEnable = 1, RdWrSense = 1, ReadNack = 1, Stop = 1, IdByte contains primary id byte, TxRxByteCount = 16), etc.

The CPU can thus program the number of bytes to be transmitted or received (up to a maximum of 20) on the LSS bus before it gets interrupted. This allows it to insert arbitrary delays in a transfer at a byte boundary. For example the CPU may want to transmit 30 bytes to a QA chip but insert a delay between the 20th and 21st bytes sent. It does this by first writing 20 bytes to the data buffer. It then writes a command to generate a START condition, send the primary id byte and then transmit the 20 bytes from the data buffer. When interrupted by the LSS block to indicate successful completion of the command the CPU can then write the remaining 10 bytes to the data

buffer. It can then wait for a defined period of time before writing a command to transmit the 10 bytes from the data buffer and generate a STOP condition to terminate the transaction over the LSS bus.

An interrupt to the CPU is generated for one cycle when any bit in *LssNIntStatus* is set. The CPU can read *LssNIntStatus* to discover the source of the interrupt. The *LssNIntStatus* registers are cleared when the CPU writes to the *LssNCmd* register. A null command write to the *LssNCmd* register will cause the *LssNIntStatus* registers to clear and no new command to start. A null command is defined as *Start*, *IdbyteEnable*, *RdWrEnable* and *Stop* all set to zero.

Table 104. LSS command register description

bit(s)	name	Description
0	Start	When 1, issue a START condition on the LSS bus.
1	ldByteEnable	ID byte transmit enable:
		1 - transmit byte in <i>IdByte</i> field
		0 - ignore byte in <i>IdByte</i> field
2	RdWrEnable	Read/write transfer enable:
		0 - ignore settings of <i>RdWrSense</i> , <i>ReadNack</i> and
		TxRxByteCount
		1 - if RdWrSense is 0, then perform a write transfer of
		TxRxByteCount bytes from the
		data buffer.
		if RdWrSense is 1, then perform a read transfer of
		TxRxByteCount bytes into the
		data buffer. Each byte should be acknowledged and
		the last byte received is
		acknowledged/not-acknowledged according to the
		setting of <i>ReadNack</i> .
3	RdWrSense	Read/write sense indicator:
		0 - write
		1 – read
4	ReadNack	Indicates, for a read transfer, whether to issue an
		acknowledge or a not-acknowledge after the last byte
		received (indicated by TxRxByteCount).
		0 - issue acknowledge after last byte received
		1 - issue not-acknowledge after last byte received.
5	Stop	When 1, issue a STOP condition on the LSS bus.
7:6	reserved	Must be 0
15:8	IdByte	Byte to be transmitted if IdByteEnable is 1. Bit 8
		corresponds to the LSB.

10

5

20:16	TxRxByteCount	Number of bytes to be transmitted from the data buffer or
		the number of bytes to be received into the data buffer.
		The maximum value that should be programmed is 20, as
		the size of the data buffer is 20 bytes. Valid values are 1
		to 20, 0 is valid when RdWrEnable = 0, other cases are
		invalid andundefined.

The data buffer is implemented in the LSS master block. When the CPU writes to the LssNBuffer registers the data written is presented to the LSS master block via the lssN_buffer_wrdata bus and configuration registers block pulses the lssN_buffer_wen bit corresponding to the register written. For example if LssNBuffer[2] is written to lssN_buffer_wen[2] will be pulsed. When the CPU reads the LssNBuffer registers the configuration registers block reflect the lssN_buffer_rdata bus back to the CPU.

19.3.3 LSS master unit

5.

15

30

The LSS master unit is instantiated for both LSS bus 0 and LSS bus 1. It controls transactions on the LSS bus by means of the state machine shown in Figure 83, which interprets the commands that are written by the CPU. It also contains a single 20 byte data buffer used for transmitting and receiving data.

The CPU can write data to be transmitted on the LSS bus by writing to the *LssNBuffer* registers. It can also read data that the LSS master unit receives on the LSS bus by reading the same registers. The LSS master always transmits or receives bytes to or from the data buffer in the same order.

For a transmit command, LssNBuffer[0][7:0] gets transmitted first, then LssNBuffer[0][15:8], LssNBuffer[0][23:16], LssNBuffer[0][31:24], LssNBuffer[1][7:0] and so on until TxRxByteCount number of bytes are transmitted. A receive command fills data to the buffer in the same order.

- Each new command the buffer start point is reset.
 - All state machine outputs, flags and counters are cleared on reset. After a reset the state machine goes to the *Reset* state and initialises the LSS pins (*Iss_clk* is set to 1, *Iss_data* is tristated and allowed to be pulled up to 1). When the reset condition is removed the state machine transitions to the *Wait* state.
- 25 It remains in the *Wait* state until *Iss_new_cmd* equals 1. If the *Start* bit of the command is 0 the state machine proceeds directly to the *CheckIdByteEnable* state. If the *Start* bit is 1 it proceeds to the *GenerateStart* state and issues a START condition on the LSS bus.

In the CheckIdByteEnable state, if the IdByteEnable bit of the command is 0 the state machine proceeds directly to the CheckRdWrEnable state. If the IdByteEnable bit is 1 the state machine enters the SendIdByte state and the byte in the IdByte field of the command is transmitted on the LSS. The WaitForIdAck state is then entered. If the byte is acknowledged, the state machine proceeds to the CheckRdWrEnable state. If the byte is not-acknowledged, the state machine proceeds to the GenerateInterrupt state and issues an interrupt to indicate a not-acknowledge was received after transmission of the primary id byte.

In the CheckRdWrEnable state, if the RdWrEnable bit of the command is 0 the state machine proceeds directly to the CheckStop state. If the RdWrEnable bit is 1, count is loaded with the value of the TxRxByteCount field of the command and the state machine enters either the ReceiveByte state if the RdWrSense bit of the command is 1 or the TransmitByte state if the RdWrSense bit is 0.

For a write transaction, the state machine keeps transmitting bytes from the data buffer, decrementing *count* after each byte transmitted, until *count* is 1. If all the bytes are successfully transmitted the state machine proceeds to the *CheckStop* state. If the slave QA chip not-acknowledges a transmitted byte, the state machine indicates this error by issuing an interrupt to the CPU and then entering the *GenerateInterrupt* state.

For a read transaction, the state machine keeps receiving bytes into the data buffer, decrementing count after each byte transmitted, until count is 1. After each byte received the LSS master must issue an acknowledge. After the last expected byte (i.e. when count is 1) the state machine checks the ReadNack bit of the command to see whether it must issue an acknowledge or not-acknowledge for that byte. The CheckStop state is then entered.

- In the *CheckStop* state, if the *Stop* bit of the command is 0 the state machine proceeds directly to the *GenerateInterrupt* state. If the *Stop* bit is 1 it proceeds to the *GenerateStop* state and issues a STOP condition on the LSS bus before proceeding to the *GenerateInterrupt* state. In both cases an interrupt is issued to indicate successful completion of the command.
- The state machine then enters the *Wait* state to await the next command. When the state machine reenters the *Wait* state the output pins (*Iss_data* and *Iss_clk*) are not changed, they retain the state of the last command. This allows the possibility of multi-command transactions. The CPU may abort the current transfer at any time by performing a write to the *Reset* register of the LSS block.
- 25 19.3.3.1 START and STOP generation

5

10

15

30

35

START and STOP conditions, which signal the beginning and end of data transmission, occur when the LSS master generates a falling and rising edge respectively on the data while the clock is high.

In the *GenerateStart* state, *Iss_gpio_clk* is held high with *Iss_gpio_e* remaining deasserted (so the data line is pulled high externally) for *LssClockHighLowDuration pclk* cycles. Then *Iss_gpio_e* is asserted and *Iss_gpio_dout* is pulled low (to drive a 0 on the data line, creating a falling edge) with *Iss_gpio_clk* remaining high for another *LssClockHighLowDuration pclk* cycles.

In the GenerateStop state, both <code>lss_gpio_clk</code> and <code>lss_gpio_dout</code> are pulled low followed by the assertion of <code>lss_gpio_e</code> to drive a 0 while the clock is low. After <code>LssClockHighLowDuration pclk</code> cycles, <code>lss_gpio_clk</code> is set high. After a further <code>LssClockHighLowDuration pclk</code> cycles, <code>lss_gpio_e</code> is deasserted to release the data bus and create a rising edge on the data bus during the high period of the clock.

If the bus is not in the required state for start and stop generation (*Iss_clk*=1, *Iss_data*=1 for start, and *Iss_clk*=1, *Iss_data*=0), the state machine moves the bus to the correct state and proceeds as

described above. Figure 82 shows the transition timing from any bus state to start and stop generation

19.3.3.2 Clock pulse generation

The LSS master holds <code>lss_gpio_clk</code> high while the LSS bus is inactive. A clock pulse is generated for each bit transmitted or received over the LSS bus. It is generated by first holding <code>lss_gpio_clk</code> low for <code>LssClockHighLowDuration pclk</code> cycles, and then high for <code>LssClockHighLowDuration pclk</code> cycles.

19.3.3.3 Data De-glitching

5

10

25

30

When data is received in the LSS block it is passed to a de-glitching circuit. The de-glitch circuit samples the data 3 times on pclk and compares the samples. If all 3 samples are the same then the data is passed, otherwise the data is ignored.

Note that the LSS data input on SoPEC is double registered in the GPIO block before being passed to the LSS.

19.3.3.4 Data reception

The input data, *gpio_lss_di*, is first synchronised to the *pclk* domain by means of two flip-flops clocked by *pclk* (the double register resides in the GPIO block). The LSS master generates a clock pulse for each bit received. The output *lss_gpio_e* is deasserted *LssClockToDataHold pclk* cycles after the falling edge of *lss_gpio_clk* to release the data bus. The value on the synchronised *gpio_lss_di* is sampled *Tstrobe* number of clock cycles after the rising edge of *lss_gpio_clk* (the data is de-glitched over a further 3 stage register to avoid possible glitch

detection). See Figure 84 for further timing information.

In the *ReceiveByte* state, the state machine generates 8 clock pulses. At each *Tstrobe* time after the rising edge of *Iss_gpio_clk* the synchronised *gpio_lss_di* is sampled. The first bit sampled is *LssNBuffer[0][7]*, the second *LssNBuffer[0][6]*, etc to *LssNBuffer[0][0]*. For each byte received the state machine either sends an NAK or an ACK depending on the command configuration and the number of bytes received.

In the *SendNack* state the state machine generates a single clock pulse. *Iss_gpio_e* is deasserted and the LSS data line is pulled high externally to issue a not-acknowledge.

In the SendAck state the state machine generates a single clock pulse. Iss_gpio_e is asserted and a 0 driven on Iss_gpio_dout after Iss_gpio_clk falling edge to issue an acknowledge.

19.3.3.5 Data transmission

The LSS master generates a clock pulse for each bit transmitted. Data is output on the LSS bus on the falling edge of *lss_gpio_clk*.

When the LSS master drives a logical zero on the bus it will assert *Iss_gpio_e* and drive a 0 on *Iss_gpio_dout* after *Iss_gpio_clk* falling edge. *Iss_gpio_e* will remain asserted and *Iss_gpio_dout* will remain low until the next *Iss_clk* falling edge.

When the LSS master drives a logical one *lss_gpio_e* should be deasserted at *lss_gpio_clk* falling edge and remain deasserted at least until the next *lss_gpio_clk* falling edge. This is because the LSS bus will be externally pulled up to logical one via a pull-up resistor.

- In the SendId byte state, the state machine generates 8 clock pulses to transmit the byte in the IdByte field of the current valid command. On each falling edge of Iss_gpio_clk a bit is driven on the data bus as outlined above. On the first falling edge IdByte[7] is driven on the data bus, on the second falling edge IdByte[6] is driven out, etc.
- In the *TransmitByte* state, the state machine generates 8 clock pulses to transmit the byte at the output of the transmit FIFO. On each falling edge of *Iss_gpio_clk* a bit is driven on the data bus as outlined above. On the first falling edge *LssNBuffer[0][7]* is driven on the data bus, on the second falling edge *LssNBuffer[0][6]* is driven out, etc on to *LssNBuffer[0][7]* bits.
- In the WaitForAck state, the state machine generates a single clock pulse. At Tstrobe time after the rising edge of Iss_gpio_clk the synchronized gpio_lss_di is sampled. A 0 indicates an acknowledge and ack_detect is pulsed, a 1 indicates a not-acknowledge and nack_detect is pulsed.

19.3.3.6 Data rate control

- The CPU can control the data rate by setting the clock period of the LSS bus clock by

 15 programming appropriate value in LssClockHighLowDuration. The default setting for the register is 200 (pclk cycles) which corresponds to transmission rate of 400kHz on the LSS bus (the lss_clk is high for LssClockHighLowDuration cycles then low for LssClockHighLowDuration cycles). The lss_clk will always have a 50:50 duty cycle. The LssClockHighLowDuration register should not be set to values less than 8.
- The hold time of *lss_data* after the falling edge of *lss_clk* is programmable by the *LssClocktoDataHold* register. This register should not be programmed to less than 2 or greater than the *LssClockHighLowDuration* value.

19.3.3.7 LSS master timing parameters

The LSS master timing parameters are shown in Figure 84 and the associated values are shown in Table 105.

Table 105. LSS master timing parameters

Parameter	Description	min	nom	max	unit
LSS Master Drivi	ng	·			<u> </u>
Тр	LSS clock period divided by 2	8	200	FFFF	pclk cycles
Tstart_delay	Time to start data edge from rising	Тр			+pclk cycles
	clock edge	LssCl	ocktoD	ataHold	
Tstop_delay	Time to stop data edge from rising	Тр			+pclk cycles

DRAM SUBSYSTEM

20 DRAM Interface Unit (DIU)

20.1 OVERVIEW

10

25

Figure 85 shows how the DIU provides the interface between the on-chip 20 Mbit embedded DRAM and the rest of SoPEC. In addition to outlining the functionality of the DIU, this chapter provides a top-level overview of the memory storage and access patterns of SoPEC and the buffering required in the various SoPEC blocks to support those access requirements.

The main functionality of the DIU is to arbitrate between requests for access to the embedded DRAM and provide read or write accesses to the requesters. The DIU must also implement the initialisation sequence and refresh logic for the embedded DRAM.

The arbitration scheme uses a fully programmable timeslot mechanism for non-CPU requesters to meet the bandwidth and latency requirements for each unit, with unused slots re-allocated to provide best effort accesses. The CPU is allowed high priority access, giving it minimum latency,

but allowing bounds to be placed on its bandwidth consumption.

The interface between the DIU and the SoPEC requesters is similar to the interface on PEC1 i.e. separate control, read data and write data busses.

The embedded DRAM is used principally to store:

- CPU program code and data.
- PEP (re)programming commands.
 - Compressed pages containing contone, bi-level and raw tag data and header information.
 - Decompressed contone and bi-level data.
 - Dotline store during a print.
 - Print setup information such as tag format structures, dither matrices and dead nozzle information.
 - 20.2 IBM Cu-11 EMBEDDED DRAM
 - 20.2.1 Single bank

SoPEC will use the 1.5 V core voltage option in IBM's 0.13 µm class Cu-11 process.

The random read/write cycle time and the refresh cycle time is 3 cycles at 160 MHz [16]. An open page access will complete in 1 cycle if the page mode select signal is clocked at 320 MHz or 2 cycles if the page mode select signal is clocked every 160 MHz cycle. The page mode select signal will be clocked at 160 MHz in SoPEC in order to simplify timing closure. The DRAM word size is 256 bits.

Most SoPEC requesters will make single 256 bit DRAM accesses (see Section 20.4). These accesses will take 3 cycles as they are random accesses i.e. they will most likely be to a different memory row than the previous access.

The entire 20 Mbit DRAM will be implemented as a single memory bank. In Cu-11, the maximum single instance size is 16 Mbit. The first 1 Mbit tile of each instance contains an area overhead so the cheapest solution in terms of area is to have only 2 instances. 16 Mbit and 4Mbit instances would together consume an area of 14.63 mm² as would 2 times 10 Mbit instances. 4 times 5 Mbit instances would require 17.2 mm².

The instance size will determine the frequency of refresh. Each refresh requires 3 clock cycles. In Cu-11 each row consists of 8 columns of 256-bit words. This means that 10 Mbit requires 5120 rows. A complete DRAM refresh is required every 3.2 ms. Two times 10 Mbit instances would require a refresh every 100 clock cycles, if the instances are refreshed in parallel.

The SoPEC DRAM will be constructed as two 10 Mbit instances implemented as a single memory bank.

15 20.3 SOPEC MEMORY USAGE REQUIREMENTS

The memory usage requirements for the embedded DRAM are shown in Table 106.

Table 106. Memory Usage Requirements

Block	Size	Description
Compressed page	2048 Kbytes	Compressed data page store for Bi-
store		level
		and contone data
Decompressed	108 Kbyte	13824 lines with scale factor 6 = 2304
Contone Store		pixels, store 12 lines, 4 colors = 108
		кВ
		13824 lines with scale factor 5 = 2765
		pixels, store 12 lines, 4 colors = 130
		kB ·
Spot line store	5.1 Kbyte	13824 dots/line so 3 lines is 5.1 kB
Tag Format Structure	Typically 12 Kbyte (2.5 mm	55 kB in for 384 dot line tags
	tags @ 800 dpi)	2.5 mm tags (1/10th inch) @ 1600 dpi
	·	require 160 dot lines = 160/384 x55 or
		23 kB
		2.5 mm tags (1/10th inch) @ 800 dpi
		require 80/384 x55 = 12 kB
Dither Matrix store	4 Kbytes	64x64 dither matrix is 4 kB
		128x128 dither matrix is 16 kB
		256x256 dither matrix is 64 kB
DNC Dead Nozzle	1.4 Kbytes	Delta encoded, (10 bit delta position +

Table		6 dead nozzle mask) x% Dnozzle
		5% dead nozzles requires (10+6)x
		692 Dnoz zles = 1.4 Kbytes
Dot-line store	369.6 Kbytes	Assume each color row is separated
		by 5 dot lines on the print head
		The dot line store will be
		0+5+1050+55 = 330 half dot lines +
		48 extra half dot lines (4 per dot row)
		+ 60 extra half dot lines estimated to
		account for printhead misalignment =
		438 half dot lines.
		438 half dot lines of 6912 dots =
		369.6Kbytes
PCU Program code	8 Kbytes	1024 commands of 64 bits = 8 kB
CPU	64 Kbytes	Program code and data
TOTAL	2620 Kbytes (12 Kbyte TFS	
	storage)	

Note:

10

 Total storage is fixed to 2560 Kbytes to align to 20 Mbit DRAM. This will mean that less space than noted in Table may be available for the compressed band store.

5 20.4 SOPEC MEMORY ACCESS PATTERNS

Table 107 shows a summary of the blocks on SoPEC requiring access to the embedded DRAM and their individual memory access patterns. Most blocks will access the DRAM in single 256-bit accesses. All accesses must be padded to 256-bits except for 64-bit CDU write accesses and CPU write accesses. Bits which should not be written are masked using the individual DRAM bit write inputs or byte write inputs, depending on the foundry. Using single 256-bit accesses means that the buffering required in the SoPEC DRAM requesters will be minimized.

Table 107. Memory access patterns of SoPEC DRAM Requesters

DRAM requester	Direction	Memory access pattern
CPU	R	Single 256-bit reads.
	W	Single 32-bit, 16-bit or 8-bit writes.
SCB	R	Single 256-bit reads.
	W	Single 256-bit writes, with byte enables.
CDU	R	Single 256-bit reads of the compressed contone data.
		Each CDU access is a write to 4 consecutive DRAM words in the same row but only 64 bits of each word are written with the remaining

		bits write masked.
		The access time for this 4 word page mode burst is $3 + 2 + 2 + 2 = 9$
		cycles if the page mode select signal is clocked at 160 MHz.
CFU	R	Single 256 bit reads.
LBD	R	Single 256 bit reads.
SFU	R	Separate single 256 bit reads for previous and current line but sharing
		the same DIU interface
	W	Single 256 bit writes.
TE(TD)	R	Single 256 bit reads. Each read returns 2 times 128 bit tags.
TE(TFS)	R	Single 256 bit reads. TFS is 136 bytes. This means there is unused
		data in the fifth 256 bit read. A total of 5 reads is required.
HCU	R	Single 256 bit reads. 128 x 128 dither matrix requires 4 reads per line
		with double buffering. 256 x 256 dither matrix requires 8 reads at the
		end of the line with single buffering.
DNC	R	Single 256 bit dead nozzle table reads. Each dead nozzle table read
		con tains 16 dead-nozzle tables entries each of 10 delta bits plus 6
		dead nozzle mask bits.
DWU	W	Single 256 bit writes since enable/disable DRAM access per color
		plane.
LLU	R	Single 256 bit reads since enable/disable DRAM access per color
		plane.
PCU	R	Single 256 bit reads. Each PCU command is 64 bits so each 256 bit
		word can contain 4 PCU commands.
		PCU reads from DRAM used for reprogramming PEP should be
		executed with minimum latency.
		If this occurs between pages then there will be free bandwidth as most
	-	of the other SoPEC Units will not be requesting from DRAM. If this
		occurs between bands then the LDB, CDU and TE bandwidth will be
		free. So the PCU should have a high priority to access to any spare
		bandwidth.
Refresh		Single refresh.
I/GII GSII	1	Single refresh.

20.5 BUFFERING REQUIRED IN SOPEC DRAM REQUESTERS

5

If each DIU access is a single 256-bit access then we need to provide a 256-bit double buffer in the DRAM requester. If the DRAM requester has a 64-bit interface then this can be implemented as an 8×64 -bit FIFO.

Table 108. Buffer sizes in SoPEC DRAM requesters

DRAM Requester	Direction	Access patterns	Buffering required in
			block

CPU	R	Single 256-bit reads.	Cache.
	W	Single 32-bit writes but allowing 16-bit or	None.
		byte addressable writes.	
SCB	R	Single 256-bit reads.	Double 256-bit buffer.
	W	Single 256-bit writes, with byte enables.	Double 256-bit buffer.
CDU	R	Single 256-bit reads of the compressed	Double 256-bit buffer.
		contone data.	
	W	Each CDU access is a write to 4	Double half JPEG block
		consecutive DRAM words in the same	buffer.
		row but only 64 bits of each word are	
		written with the remaining bits write	
		masked.	
CFU	R	Single 256 bit reads.	Triple 256-bit buffer.
LBD	R	Single 256 bit reads.	Double 256-bit buffer.
SFU	R	Separate single 256 bit reads for	Double 256-bit buffer for
		previous and cur rent line but sharing	each read channel.
		the same DIU interface	
	W	Single 256 bit writes.	Double 256-bit buffer.
TE(TD)	R	Single 256 bit reads.	Double 256-bit buffer.

Notes:

10

- 1: The number of allocated timeslots is based on 64 timeslots each of 1 bit/cycle but broken down to a granularity of 0.25 bit/cycle. Bandwidth is allocated based on peak bandwidth.
- 2: Wire-speed bandwidth for a 4 wire SCB configuration is 32 Mbits/s for each wire plus 12 Mbit/s for USB. This is a maximum of 138 Mbit/s. The maximum effective data rate is 26 Mbits/s for each wire plus 8 Mbit/s for USB. This is 112 Mbit/s. 112 Mbit/s is 0.734 bits/cycle or 256 bits every 348 cycles.
 - 3: Wire-speed bandwidth for a 2 wire SCB configuration is 32 Mbits/s for each wire plus 12 Mbit/s for USB. This is a maximum of 74 Mbit/s. The maximum effective data rate is 26 Mbits/s for each wire plus 8 Mbit/s for USB. This is 60 Mbit/s. 60 Mbit/s is 0.393 bits/cycle or 256 bits every 650 cycles.
 - 4: At 1:1 compression CDU must read a 4 color pixel (32 bits) every SF² cycles.
 - 5: At 10:1 average compression CDU must read a 4 color pixel (32 bits) every 10*SF² cycles.
 - 6: 4 color pixel (32 bits) is required, on average, by the CFU every SF² (scale factor) cycles.
- The time available to write the data is a function of the size of the buffer in DRAM. 1.5 buffering means 4 color pixel (32 bits) must be written every SF²/2 (scale factor) cycles. Therefore, at a scale factor of SF, 64 bits are required every SF² cycles.

Since 64 valid bits are written per 256-bit write (Figure n page 379 on page Error! B kmark not defined.) then the DRAM is accessed every SF² cycles i.e. at SF4 an access every 16 cycles, at SF6 an access every 36 cycles.

If a page mode burst of 4 accesses is used then each access takes (3 + 2 + 2 +2) equals 9 cycles. This means at SF, a set of 4 back-to-back accesses must occur every 4*SF² cycles. This assumes the page mode select signal is clocked at 160 MHz. CDU timeslots therefore take 9 cycles.

For scale factors lower than 4 double buffering will be used.

- 7: The peak bandwidth is twice the average bandwidth in the case of 1.5 buffering.
- 8: Each CDU(W) burst takes 9 cycles instead of 4 cycles for other accesses so CDU timeslots are longer.
 - 9: 4 color pixel (32 bits) read by CFU every SF cycles. At SF4, 32 bits is required every 4 cycles or 256 bits every 32 cycles. At SF6, 32bits every 6 cycles or 256 bits every 48 cycles.
 - 10: At 1:1 compression require 1 bit/cycle or 256 bits every 256 cycles.
- 15 11: The average bandwidth required at 10:1 compression is 0.1 bits/cycle.
 - 12: Two separate reads of 1 bit/cycle.
 - 13: Write at 1 bit/cycle.

5

- 14: Each tag can be consumed in at most 126 dot cycles and requires 128 bits. This is a maximum rate of 256 bits every 252 cycles.
- 20 15: 17 x 64 bit reads per line in PEC1 is 5 x 256 bit reads per line in SoPEC. Double-line buffered storage.
 - 16: 128 bytes read per line is 4 x 256 bit reads per line. Double-line buffered storage.
 - 17: 5% dead nozzles 10-bit delta encoded stored with 6-bit dead nozzle mask requires 0.8 bits/cycle read access or a 256-bit access every 320 cycles. This assumes the dead nozzles are evenly spaced out. In practice dead nozzles are likely to be clumped. Peak bandwidth is estimated as 3 times average bandwidth.
 - 18: 6 bits/cycle requires 6 x 256 bit writes every 256 cycles.
 - 19: 6 bits/160 MHz SoPEC cycle average but will peak at 2 x 6 bits per 106 MHz print head cycle or 8 bits/ SoPEC cycle. The PHI can equalise the DRAM access rate over the line so that the peak rate equals the average rate of 6 bits/ cycle. The print head is clocked at an effective speed of 106 MHz.
 - 20: Assume one 256 read per 256 cycles is sufficient i.e. maximum latency of 256 cycles per access is allowable.
- 21: Refresh must occur every 3.2 ms. Refresh occurs row at a time over 5120 rows of 2 parallel
 35 10 Mbit instances. Refresh must occur every 100 cycles. Each refresh takes 3 cycles.

PCU		

Table 110 shows the DIU requesters in SoPEC. There are 12 read requesters and 5 write requesters in SoPEC as compared with 8 read requesters and 4 write requesters in PEC1. Refresh is an additional requester.

In PEC1, the interface between the DIU and the DIU requesters had the following main features:

- separate control and address signals per DIU requester multiplexed in the DIU according to the arbitration scheme,
 - separate 64-bit write data bus for each DRAM write requester multiplexed in the DIU,
 - common 64-bit read bus from the DIU with separate enables to each DIU read requester.

Timing closure for this bussing scheme was straight-forward in PEC1. This suggests that a similar scheme will also achieve timing closure in SoPEC. SoPEC has 5 more DRAM requesters but it will be in a 0.13 um process with more metal layers and SoPEC will run at approximately the same speed as PEC1.

Using 256-bit busses would match the data width of the embedded DRAM but such large busses may result in an increase in size of the DIU and the entire SoPEC chip. The SoPEC requestors would require double 256-bit wide buffers to match the 256-bit busses. These buffers, which must be implemented in flip-flops, are less area efficient than 8-deep 64-bit wide register arrays which can be used with 64-bit busses. SoPEC will therefore use 64-bit data busses. Use of 256-bit busses would however simplify the DIU implementation as local buffering of 256-bit DRAM data would not be required within the DIU.

20 20.7.1.1 CPU DRAM access

10

15

The CPU is the only DIU requestor for which access latency is critical. All DIU write requesters transfer write data to the DIU using separate point-to-point busses. The CPU will use the $cpu_dataout[31:0]$ bus. CPU reads will not be over the shared 64-bit read bus. Instead, CPU reads will use a separate 256-bit read bus.

25 20.7.2 Making more efficient use of DRAM bandwidth

The embedded DRAM is 256-bits wide. The 4 cycles it takes to transfer the 256-bits over the 64-bit data busses of SoPEC means that effectively each access will be at least 4 cycles long. It takes only 3 cycles to actually do a 256-bit random DRAM access in the case of IBM DRAM.

20.7.2.1 Common read bus

- If we have a common read data bus, as in PEC1, then if we are doing back to back read accesses the next DRAM read cannot start until the read data bus is free. So each DRAM read access can occur only every 4 cycles. This is shown in Figure 86 with the actual DRAM access taking 3 cycles leaving 1 unused cycle per access.
 - 20.7.2.2 Interleaving CPU and non-CPU read accesses
- The CPU has a separate 256-bit read bus. All other read accesses are 256-bit accesses are over a shared 64-bit read bus. Interleaving CPU and non-CPU read accesses means the effective duration of an interleaved access timeslot is the DRAM access time (3 cycles) rather than 4 cycles.
 - Figure 87 shows interleaved CPU and non-CPU read accesses.
- 15 20.7.2.3 Interleaving read and write accesses
 - Having separate write data busses means write accesses can be interleaved with each other and with read accesses. So now the effective duration of an interleaved access timeslot is the DRAM access time (3 cycles) rather than 4 cycles. Interleaving is achieved by ordering the DIU arbitration slot allocation appropriately.
- Figure 88 shows interleaved read and write accesses. Figure 89 shows interleaved write accesses.

256-bit write data takes 4 cycles to transmit over 64-bit busses so a 256-bit buffer is required in the DIU to gather the write data from the write requester. The exception is CPU write data which is transferred in a single cycle.

Figure 89 shows multiple write accesses being interleaved to obtain 3 cycle DRAM access. Since two write accesses can overlap two sets of 256-bit write buffers and multiplexors to connect two write requestors simultaneously to the DIU are required.

Write requestors only require approximately one third of the total non-CPU bandwidth. This means that a rule can be introduced such that non-CPU write requestors are not allocated adjacent timeslots. This means that a single 256-bit write buffer and multiplexor to connect the one write requestor at a time to the DIU is all that is required.

Note that if the rule prohibiting back-to-back non-CPU writes is not adhered to, then the second write slot of any attempted such pair will be disregarded and re-allocated under the unused read round-robin scheme.

20.7.3 Bus widths summary

25

30

35

20.7.4 Conclusions

5

15

Timeslots should be programmed to maximise interleaving of shared read bus accesses with other accesses for 3 cycle DRAM access. The interleaving is achieved by ordering the DIU arbitration slot allocation appropriately. CPU arbitration has been designed to maximise interleaving with non-CPU requesters

20.8 SOPEC DRAM ADDRESSING SCHEME

The embedded DRAM is composed of 256-bit words. However the CPU-subsystem may need to write individual bytes of DRAM. Therefore it was decided to make the DIU byte addressable. 22 bits are required to byte address 20 Mbit of DRAM.

Most blocks read or write 256 bit words of DRAM. Therefore only the top 17 bits i.e. bits 21 to 5 are required to address 256-bit word aligned locations.

The exceptions are

- CDU which can write 64-bits so only the top 19 address bits i.e. bits 21-3 are required.
- CPU writes can be 8, 16 or 32-bits. The *cpu_diu_wmask[1:0]* pins indicate whether to write 8, 16 or 32 bits.

All DIU accesses must be within the same 256-bit aligned DRAM word. The exception is the CDU write access which is a write of 64-bits to each of 4 contiguous 256-bit DRAM words.

20.8.1 Write Address Constaints Specific to the CDU

Note the following conditions which apply to the CDU write address, due to the four masked pagemode writes which occur whenever a CDU write slot is arbitrated.

- The CDU address presented to the DIU is cdu_diu_wadr[21:3].
- Bits [4:3] indicate which 64-bit segment out of 256 bits should be written in 4 successive masked page-mode writes.
- Each 10-Mbit DRAM macro has an input address port of width [15:0]. Of these bits, [2:0]
 are the "page address". Page-mode writes, where you just vary these LSBs (i.e. the "page" or column address), but keep the rest of the address constant, are faster than random writes. This is taken advantage of for CDU writes.

- To guarantee against trying to span a page boundary, the DIU treats "cdu_diu_wadr[6:5]" as being fixed at "00".
- From cdu_diu_wadr[21:3], a initial address of cdu_diu_wadr[21:7], concatenated with "00", is used as the starting location for the first CDU write. This address is then auto-incremented a further three times.

20.9 DIU PROTOCOLS

The DIU protocols are

5

25

- Pipelined i.e. the following transaction is initiated while the previous transfer is in progress.
- Split transaction i.e. the transaction is split into independent address and data transfers.
- 10 20.9.1 Read Protocol except CPU

The SoPEC read requestors, except for the CPU, perform single 256-bit read accesses with the read data being transferred from the DIU in 4 consecutive cycles over a shared 64-bit read bus, diu_data[63:0]. The read address <unit>_diu_radr[21:5] is 256-bit aligned.

The read protocol is:

- <unit>_diu_rreq is asserted along with a valid <unit>_diu_radr[21:5].
 - The DIU acknowledges the request with diu_<unit>_rack. The request should be deasserted. The minimum number of cycles between <unit>_diu_rreq being asserted and the DIU generating an diu_<unit>_rack strobe is 2 cycles (1 cycle to register the request, 1 cycle to perform the arbitration see Section 20.14.10).
- The read data is returned on diu_data[63:0] and its validity is indicated by diu_<unit>_rvalid. The overall 256 bits of data are transferred over four cycles in the order: [63:0] -> [127:64] -> [191:128] -> [255:192].
 - When four diu_<unit>_rvalid pulses have been received then if there is a further request <unit>_diu_rreq should be asserted again. diu_<unit>_rvalid will be always be asserted by the DIU for four consecutive cycles. There is a fixed gap of 2 cycles between diu_<unit>_rack and the first diu_<unit>_rvalid pulse. For more detail on the timing of such reads and the implications for back-to-back sequences, see Section 20.14.10.

20.9.2 Read Protocol for CPU

The CPU performs single 256-bit read accesses with the read data being transferred from the DIU over a dedicated 256-bit read bus for DRAM data, dram_cpu_data[255:0]. The read address cpu_adr[21:5] is 256-bit aligned.

The CPU DIU read protocol is:

- cpu_diu_rreq is asserted along with a valid cpu_adr[21:5].
- The DIU acknowledges the request with diu_cpu_rack. The request should be deasserted.

 The minimum number of cycles between cpu_diu_rreq being asserted and the DIU generating a cpu_diu_rack strobe is 1 cycle (1 cycle to perform the arbitration see Section 20.14.10).
 - The read data is returned on dram_cpu_data[255:0] and its validity is indicated by diu_cpu_rvalid.

- When the diu_cpu_rvalid pulse has been received then if there is a further request cpu_diu_rreq should be asserted again. The diu_cpu_rvalid pulse with a gap of 1 cycle after rack (1 cycle for the read data to be returned from the DRAM see Section 20.14.10).

 20.9.3 Write Protocol except CPU and CDU
- The SoPEC write requestors, except for the CPU and CDU, perform single 256-bit write accesses with the write data being transferred to the DIU in 4 consecutive cycles over dedicated point-to-point 64-bit write data busses. The write address <unit>_diu_wadr[21:5] is 256-bit aligned. The write protocol is:
 - <unit>_diu_wreq is asserted along with a valid <unit>_diu_wadr[21:5].
- The DIU acknowledges the request with diu_<unit>_wack. The request should be deasserted. The minimum number of cycles between <unit>_diu_wreq being asserted and the DIU generating an diu_<unit>_wack strobe is 2 cycles (1 cycle to register the request, 1 cycle to perform the arbitration see Section 20.14.10).
- In the clock cycles following diu_<unit>_wack the SoPEC Unit outputs the
 <unit>_diu_data[63:0], asserting <unit>_diu_wvalid. The first <unit>_diu_wvalid pulse can occur the clock cycle after diu_<unit>_wack. <unit>_diu_wvalid remains asserted for the following 3 clock cycles. This allows for reading from an SRAM where new data is available in the clock cycle after the address has changed e.g. the address for the second 64-bits of write data is available the cycle after diu_<unit>_wack meaning the second 64-bits of write
 data is a further cycle later. The overall 256 bits of data is transferred over four cycles in the order: [63:0] -> [127:64] -> [191:128] -> [255:192].
 - Note that for SCB writes, each 64-bit quarter-word has an 8-bit byte enable mask associated with it. A different mask is used with each quarter-word. The 4 mask values are transferred along with their associated data, as shown in Figure 92.
- If four consecutive <unit>_diu_wvalid pulses are not provided by the requester, then the arbitration logic will disregard the write and re-allocate the slot under the unused read round-robin scheme.

Once all the write data has been output then if there is a further request <unit>_diu_wreq should be asserted again.

30 20.9.4 CPU Write Protocol

35

The CPU performs single 128-bit writes to the DIU on a dedicated write bus, cpu_diu_wdata[127:0]. There is an accompanying write mask, cpu_diu_wmask[15:0], consisting of 16 byte enables and the CPU also supplies a 128-bit aligned write address on cpu_diu_wadr[21:4]. Note that writes are posted by the CPU to the DIU and stored in a 1-deep buffer. When the DAU subsequently arbitrates in favour of the CPU, the contents of the buffer are written to DRAM.

The CPU write protocol, illustrated in Figure 93., is as follows :-

• The DIU signals to the CPU via diu_cpu_write_rdy that its write buffer is empty and that the CPU may post a write whenever it wishes.

- The CPU asserts *cpu_diu_wdatavalid* to enable a write into the buffer and to confirm the validity of the write address, data and mask.
- The DIU de-asserts diu_cpu_write_rdy in the following cycle to indicate that its buffer is full and that the posted write is pending execution.
- When the CPU is next awarded a DRAM access by the DAU, the buffer's contents are
 written to memory. The DIU re-asserts diu_cpu_write_rdy once the write data has been
 captured by DRAM, namely in the "MSN1" DCU state.
 - The CPU can then, if it wishes, asynchronously use the new value of .diu_cpu_write_rdy to enable a new posted write in the same "MSN1" cycle.
- 10 20.9.5 CDU Write Protocol

The CDU performs four 64-bit word writes to 4 contiguous 256-bit DRAM addresses with the first address specified by $cdu_diu_wadr[21:3]$. The write address $cdu_diu_wadr[21:5]$ is 256-bit aligned with bits $cdu_diu_wadr[4:3]$ allowing the 64-bit word to be selected.

The write protocol is:

- cdu_diu_wdata is asserted along with a valid cdu_diu_wadr[21:3].
 - The DIU acknowledges the request with diu_cdu_wack. The request should be deasserted. The minimum number of cycles between cdu_diu_wreq being asserted and the DIU generating an diu_cdu_wack strobe is 2 cycles (1 cycle to register the request, 1 cycle to perform the arbitration see Section 20.14.10).
- In the clock cycles following diu_cdu_wack the CDU outputs the cdu_diu_data[63:0], together with asserted cdu_diu_wvalid. The first cdu_diu_wvalid pulse can occur the clock cycle after diu_cdu_wack. cdu_diu_wvalid remains asserted for the following 3 clock cycles. This allows for reading from an SRAM where new data is available in the clock cycle after the address has changed e.g. the address for the second 64-bits of write data is available the cycle after diu_cdu_wack meaning the second 64-bits of write data is a further cycle later. Data is transferred over the 4-cycle window in an order, such that each successive 64 bits will be written to a monotonically increasing (by 1 location) 256-bit DRAM word.
 - If four consecutive *cdu_diu_wvalid* pulses are not provided with the data, then the arbitration logic will disregard the write and re-allocate the slot under the unused read round-robin scheme.
 - Once all the write data has been output then if there is a further request cdu_diu_wreq should be asserted again.

20.10 DIU ARBITRATION MECHANISM

30

The DIU will arbitrate access to the embedded DRAM. The arbitration scheme is outlined in the next sections.

20.10.1 Timeslot based arbitration scheme

Table summarised the bandwidth requirements of the SoPEC requestors to DRAM. If we allocate the DIU requestors in terms of peak bandwidth then we require 35.25 bits/cycle (at SF =6) and 40.75 bits/ cycle (at SF = 4) for all the requestors except the CPU.

A timeslot scheme is defined with 64 main timeslots. The number of used main timeslots is programmable between 1 and 64.

Since DRAM read requestors, except for the CPU, are connected to the DIU via a 64-bit data bus each 256-bit DRAM access requires 4 *pclk* cycles to transfer the read data over the shared read

5 bus. The timeslot rotation period for 64 timeslots each of 4 *pclk* cycles is 256 *pclk* cycles or 1.6 μs, assuming *pclk* is 160 MHz. Each timeslot represents a 256-bit access every 256 *pclk* cycles or 1 bit/cycle. This is the granularity of the majority of DIU requestors bandwidth requirements in Table .

The SoPEC DIU requesters can be represented using 4 bits (Table n page 288 on page 268).

10 Using 64 timeslots means that to allocate each timeslot to a requester, a total of 64 x 5-bit configuration registers are required for the 64 main timeslots.

Timeslot based arbitration works by having a pointer point to the current timeslot. When rearbitration is signaled the arbitration winner is the current timeslot and the pointer advances to the next timeslot. Each timeslot denotes a single access. The duration of the timeslot depends on the access.

Note that advancement through the timeslot rotation is dependent on an enable bit, *RotationSync*, being set. The consequences of clearing and setting this bit are described in section 20.14.12.2.1 on page 295.

If the SoPEC Unit assigned to the current timeslot is not requesting then the unused timeslot arbitration mechanism outlined in Section 20.10.6 is used to select the arbitration winner.

Note that there is *always* an arbitration winner for every slot. This is because the unused read reallocation scheme includes refresh in its round-robin protocol. If all other blocks are not requesting, an early refresh will act as fall-back for the slot.

20.10.2 Separate read and write arbitration windows

15

40

For write accesses, except the CPU, 256-bits of write data are transferred from the SoPEC DIU write requestors over 64-bit write busses in 4 clock cycles. This write data transfer latency means that writes accesses, except for CPU writes and also the CDU, must be arbitrated 4 cycles in advance. (The CDU is an exception because CDU writes can start once the first 64-bits of write data have been transferred since each 64-bits is associated with a write to a different 256-bit word).

Since write arbitration must occur 4 cycles in advance, and the minimum duration of a timeslot duration is 3 cycles, the arbitration rules must be modified to initiate write accesses in advance. Accordingly, there is a write timeslot lookahead pointer shown in Figure 96 two timeslots in advance of the current timeslot pointer.

The following examples illustrate separate read and write timeslot arbitration with no adjacent write timeslots. (Recall rule on adjacent write timeslots introduced in Section 20.7.2.3 on page 238.)

In Figure 97 writes are arbitrated two timeslots in advance. Reads are arbitrated in the same timeslot as they are issued. Writes can be arbitrated in the same timeslot as a read. During arbitration the command address of the arbitrated SoPEC Unit is captured.

Other examples are shown in Figure 98 and Figure 99. The actual timeslot order is always the same as the programmed timeslot order i.e. out of order accesses do not occur and data coherency is never an issue.

Each write must always incur a latency of two timeslots.

10

15

20

5 Startup latency may vary depending on the position of the first write timeslot. This startup latency is not important.

Table 112 shows the 4 scenarios depending on whether the current timeslot and write timeslot lookahead pointers point to read or write accesses.

Table 112. Arbitration with separate windows for read and write accesses

current timeslot pointer	write timeslot lookahead pointer	actions
Read	write	Initiate DRAM read, Initiate write arbitration
Read1	read2	Initiate DRAM read1.
Write1	write2	Initiate write2 arbitration. Execute DRAM write1.
Write	read	Execute DRAM write.

If the current timeslot pointer points to a read access then this will be initiated immediately.

If the write timeslot lookahead pointer points to a write access then this access is arbitrated immediately, or immediately after the read access associated with the current timeslot pointer is initiated.

When a write access is arbitrated the DIU will capture the write address. When the current timeslot pointer advances to the write timeslot then the actual DRAM access will be initiated.

Writes will therefore be arbitrated 2 timeslots in advance of the DRAM write occurring.

At initialisation, the write lookahead pointer points to the first timeslot. The current timeslot pointer is invalid until the write lookahead pointer advances to the third timeslot when the current timeslot pointer will point to the first timeslot. Then both pointers advance in tandem.

CPU write accesses are excepted from the lookahead mechanism.

If the selected SoPEC Unit is not requesting then there will be separate read and write selection for unused timeslots. This is described in Section 20.10.6.

25 20.10.3 Arbitration of CPU accesses

What distinguishes the CPU from other SoPEC requestors, is that the CPU requires minimum latency DRAM access i.e. preferably the CPU should get the next available timeslot whenever it requests.

The minimum CPU read access latency is estimated in Table 113. This is the time between the CPU making a request to the DIU and receiving the read data back from the DIU.

Table 113. Estimated CPU read access latency ignoring caching

CPU read access latency	Duration
CPU cache miss	1 cycle
CPU MMU logic issues request and	1 cycle
DIU arbitration completes	
Transfer the read address to the DRAM	1 cycle
DRAM read latency	1 cycle
Register the read data in CPU bridge	1 cycle
Register the read data in CPU	1 cycle
CPU cache miss	1 cycle
CPU MMU logic issues request and	1 cycle
DIU arbitration completes	
TOTAL gap between requests	6 cycles

If the CPU, as is likely, requests DRAM access again immediately after receiving data from the DIU then the CPU could access every second timeslot if the access latency is 6 cycles. This assumes that interleaving is employed so that timeslots last 3 cycles. If the CPU access latency were 7 cycles, then the CPU would only be able to access every third timeslot.

If a cache hit occurs the CPU does not require DRAM access. For its next DIU access it will have to wait for its next assigned DIU slot. Cache hits therefore will reduce the number of DRAM accesses but not speed up any of those accesses.

To avoid the CPU having to wait for its next timeslot it is desirable to have a mechanism for ensuring that the CPU always gets the next available timeslot without incurring any latency on the non-CPU timeslots.

This can be done by defining each timeslot as consisting of a CPU access preceding a non-CPU access. Each timeslot will last 6 cycles i.e. a CPU access of 3 cycles and a non-CPU access of 3 cycles. This is exactly the interleaving behaviour outlined in Section 20.7.2.2. If the CPU does not require an access, the timeslot will take 3 or 4 and the timeslot rotation will go faster. A summary is given in Table 114.

Table 114. Timeslot access times.

20

5

10

15

Access	Duration	Explanation
CPU access + non-CPU access	3 + 3 = 6 cycles	Interleaved access
non-CPU access	4 cycles	Access and preceding access both to shared read bus
non-CPU access	3 cycles	Access and preceding access not both to shared read bus
CDU write access	3+2+2+2 = 9 cycles	Page mode select signal is clocked at 160

 MHz	٦
	- 1

CDU write accesses require 9 cycles. CDU write accesses preceded by a CPU access require 12 cycles. CDU timeslots therefore take longer than all other DIU requestors timeslots.

With a 256 cycle rotation there can be 42 accesses of 6 cycles.

are reset to their respective initial values.

5

10·

For low scale factor applications, it is desirable to have more timeslots available in the same 256 cycle rotation. So two counters of 4-bits each are defined allowing the CPU to get a maximum of (CPUPreAccessTimeslots + 1) pre-accesses for every (CPUTotalTimeslots + 1) main slots. A timeslot counter starts at CPUTotalTimeslots and decrements every timeslot, while another counter starts at CPUPreAccessTimeslots and decrements every timeslot in which the CPU uses its access. When the CPU pre-access counter goes to zero before CPUTotalTimeslots, no further CPU accesses are allowed. When the CPUTotalTimeslots counter reaches zero both counters

The CPU is not included in the list of SoPEC DIU requesters, Table , for the main timeslot allocations. The CPU cannot therefore be allocated main timeslots. It relies on pre-accesses in advance of such slots as the sole method for DRAM transfers.

- 15 CPU access to DRAM can never be fully disabled, since to do so would render SoPEC inoperable. Therefore the CPUPreAccessTimeslots and CPUTotalTimeslots register values are interpreted as follows: In each succeeding window of (CPUTotalTimeslots+ 1) slots, the maximum quota of CPU pre-accesses allowed is (CPUPreAccessTimeslots+ 1). The "+ 1" implementations mean that the CPU quota cannot be made zero.
- The various modes of operation are summarised in Table 115 with a nominal rotation period of 256 cycles.

Table 115. CPU timeslot allocation modes with nominal rotation period of 256 cycles

Access Type	Nominal	Number of	Notes
	Timeslot	timeslots	
	duration		
CPU Pre-access	6 cycles	42 timeslots	Each access is CPU + non-CPU.
i.e.			If CPU does not use a timeslot then
CPUPreAccessTimesIo			rotation is faster.
ts = CPUTotalTimeslots	;		
Fractional CPU Pre-	4 or 6	42-64 timeslots	Each CPU + non-CPU access
access	cycles		requires a 6 cycle
i.e.			timeslot.
CPUPreAccessTimeslo			
ts < CPUTotalTimeslots	;		
			Individual non-CPU timeslots take 4
			cycles if

current access and preceding
access are both
to shared read bus.
Individual non-CPU timeslots take 3
cycles if
current access and preceding
access are not both
to shared read bus.

20.10.4 CDU accesses

5

As indicated in Section 20.10.3, CDU write accesses require 9 cycles. CDU write accesses preceded by a CPU access require 12 cycles. CDU timeslots therefore take longer than all other DIU requestors timeslots. This means that when a write timeslot is unused it cannot be reallocated to a CDU write as CDU accesses take 9 cycles. The write accesses which the CDU write could otherwise replace require only 3 or 4 cycles.

Unused CDU write accesses can be replaced by any other write access according to 20.10.6.1 Unused write timeslots allocation on page 247.

20.10.5 Refresh controller

Refresh is not included in the list of SoPEC DIU requesters, Table , for the main timeslot allocations. Timeslots cannot therefore be allocated to refresh.

The DRAM must be refreshed every 3.2 ms. Refresh occurs row at a time over 5120 rows of 2 parallel 10 Mbit instances. A refresh operation must therefore occur every 100 cycles. The *refresh_period* register has a default value of 99. Each refresh takes 3 cycles.

- A refresh counter will count down the number of cycles between each refresh. When the down-counter reaches 0, the refresh controller will issue a refresh request and the down-counter is reloaded with the value in *refresh_period* and the count-down resumes immediately. Allocation of main slots must take into account that a refresh is required at *least* once every 100 cycles.
- Refresh is included in the unused read and write timeslot allocation. If unused timeslot allocation results in refresh occurring early by *N* cycles, then the refresh counter will have counted down to *N*. In this case, the refresh counter is reset to *refresh_period* and the count-down recommences. Refresh can be preceded by a CPU access in the same way as any other access. This is controlled by the *CPUPreAccessTimeslots* and *CPUTotalTimeslots* configuration registers. Refresh will therefore not affect CPU performance. A sequence of accesses including refresh
- 25 might therefore be CPU, refresh, CPU, actual timeslot.
 - 20.10.6 Allocating unused timeslots

Unused slots are re-allocated separately depending on whether the unused access was a read access or a write access. This is best-effort traffic. Only unused non-CPU accesses are reallocated.

30 20.10.6.1 Unused write timeslots allocation

Unused write timeslots are re-allocated according to a $\it fixed$ priority order shown in Table 116 .

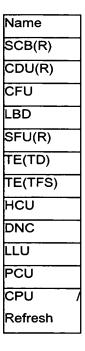

Table 116. Unused write timeslot priority order

Name	Priority
•	Order
SCB(W)	1
SFU(W)	2
DWU	3
Unused read timeslot allocation	4

CDU write accesses cannot be included in the unused timeslot allocation for write as CDU accesses take 9 cycles. The write accesses which the CDU write could otherwise replace require only 3 or 4 cycles.

- Unused write timeslot allocation occurs two timeslots in advance as noted in Section 20.10.2. If the units at priorities 1-3 are not requesting then the timeslot is re-allocated according to the unused read timeslot allocation scheme described in Section 20.10.6.2. However, the unused read timeslot allocation will occur when the current timeslot pointer of Figure 96 reaches the timeslot i.e. it will not occur in advance.
- 10 20.10.6.2 Unused read timeslots allocation
 Unused read timeslots are re-allocated according to a two level round-robin scheme. The SoPEC
 Units included in read timeslot re-allocation is shown in Table 117.

15 Table 117. Unused read timeslot allocation

Each SoPEC requestor has an associated bit, *ReadRoundRobinLevel*, which indicates whether it is in level 1 or level 2 round-robin.

Table 118. Read round-robin level selection

Level	Action
ReadRoundRobinLevel = 0	Level 1
ReadRoundRobinLevel = 1	Level 2

A pointer points to the most recent winner on each of the round-robin levels. Re-allocation is carried out by traversing level 1 requesters, starting with the one immediately succeeding the last level 1 winner. If a requesting unit is found, then it wins arbitration and the level 1 pointer is shifted to its position. If no level 1 unit wants the slot, then level 2 is similarly examined and its pointer adjusted.

Since refresh occupies a (shared) position on one of the two levels and continually requests access, there will always be some round-robin winner for any unused slot.

20.10.6.2.1 Shared CPU / Refresh Round-Robin Position

Note that the CPU can conditionally be allowed to take part in the unused read round-robin scheme. Its participation is controlled via the configuration bit *EnableCPURoundRobin*. When this bit is set, the CPU and refresh *share* a joint position in the round-robin order, shown in Table

When cleared, the position is occupied by refresh alone.

If the shared position is next in line to be awarded an unused non-CPU read/write slot, then the CPU will have first option on the slot. Only if the CPU doesn't want the access, will it be granted to refresh. If the CPU is excluded from the round robin, then any awards to the position benefit refresh.

20 20.11 GUIDELINES FOR PROGRAMMING THE DIU

Some guidelines for programming the DIU arbitration scheme are given in this section together with an example.

20.11.1 Circuit Latency

10

25

30

35

Circuit latency is a fixed service delay which is incurred, as and from the acceptance by the DIU arbitration logic of a block's pending read/write request. It is due to the processing time of the request, readying the data, plus the DRAM access time. Latencies differ for read and write requests. See Tables 79 and 80 for respective breakdowns.

If a requesting block is currently stalled, then the *longest* time it will have to wait between issuing a new request for data and actually receiving it would be its timeslot period, plus the circuit latency overhead, along with any intervening non-standard slot durations, such as refresh and CDU(W). In any case, a stalled block will always incur this latency as an additional overhead, when coming out of a stall.

In the case where a block starts up or unstalls, it will start processing newly-received data at a time beyond its serviced timeslot equivalent to the circuit latency. If the block's timeslots are evenly spaced apart in time to match its processing rate, (in the hope of minimising stalls,) then

the earliest that the block could restall, if not re-serviced by the DIU, would be the same latency delay beyond its next timeslot occurrence. Put another way, the latency incurred at start-up pushes the potential DIU-induced stall point out by the same fixed delta beyond each successive timeslot allocated to the block. This assumes that a block re-requests access well in advance of its upcoming timeslots. Thus, for a given stall-free run of operation, the circuit latency overhead is only incurred inititially when unstalling.

5

10

15

20

25

35

40

While a block can be stalled as a result of how quickly the DIU services its DRAM requests, it is also prone to stalls caused by its upstream or downstream neighbours being able to supply or consume data which is transferred between the blocks directly, (as opposed to via the DIU). Such neighbour-induced stalls, often occurring at events like end of line, will have the effect that a block's DIU read buffer will tend to fill, as the block stops processing read data. Its DIU write buffer will also tend to fill, unable to despatch to DRAM until the downstream block frees up shared-access DRAM locations. This scenario is beneficial, in that when a block unstalls as a result of its neighbour releasing it, then that block's read/write DIU buffers will have a fill state less likely to stall it a second time, as a result of DIU service delays.

A block's slots should be scheduled with a *service guarantee* in mind. This is dictated by the block's processing rate and hence, required access to the DRAM. The rate is expressed in terms of bits per cycle across a processing window, which is typically (though not always) 256 cycles. Slots should be evenly interspersed in this window (or "rotation") so that the DIU can fulfill the block's service needs.

The following ground rules apply in calculating the distribution of slots for a given non-CPU block:-

• The block can, at maximum, suffer a stall *once* in the rotation, (i.e. unstall and restall) and hence incur the circuit latency described above.

This rule is, by definition, always fulfilled by those blocks which have a service requirement of only 1 bit/cycle (equivalent to 1 slot/rotation) or fewer. It can be shown that the rule is also satisfied by those blocks requiring more than 1 bit/cycle. See Section 20.12.1 Slot Distributions and Stall Calculations for Individual Blocks, on page 255.

- Within the rotation, certain slots will be unavailable, due to their being used for refresh.
 (See Section 20.11.2 Refresh latencies)
- In programming the rotation, account must be taken of the fact that any CDU(W) accesses
 will consume an extra 6 cycles/access, over and above the norm, in CPU pre-access mode,
 or 5 cycles/access without pre-access.
 - The total delay overhead due to latency, refreshes and CDU(W) can be factored into the service guarantee for all blocks in the rotation by deleting once, (i.e. reducing the rotation window,) that number of slots which equates to the cumulative duration of these various anomalies.
 - The use of lower scale factors will imply a more frequent demand for slots by non-CPU blocks. The percentage of slots in the overall rotation which can therefore be designated as CPU pre-access ones should be calculated last, based on what can be accommodated in the light of the non-CPU slot need.

Read latency is summarised below in Table 119 .

Table 119. Read latency

Non-CPU read access latency	Duration
non-CPU read requestor internally	1 cycle
generates DIU request	
register the non- CPU read request	1 cycle
complete the arbitration of the request	1 cycle
transfer the read address to the DRAM	1 cycle
DRAM read latency	1 cycle
register the DRAM read data in DIU	1 cycle
register the 1st 64-bits of read data in	1 cycle
requester	
register the 2nd 64-bits of read data in	1 cycle
requester	
register the 3rd 64-bits of read data in	1 cycle
requester	
register the 4th 64-bits of read data in	1 cycle
requester	
TOTAL	10 cycles

5 Write latency is summarised in Table 120.

Table 120. Write latency

Non-CPU write access latency	Duration
non-CPU write requestor internally generates DIU request	1 cycle
register the non-CPU write request	1 cycle
complete the arbitration of the request	1 cycle
transfer the acknowledge to the write requester	1 cycle
transfer the 1st 64 bits of write data to the DIU	1 cycle
transfer the 2nd 64 bits of write data to the DIU	1 cycle
transfer the 3rd 64 bits of write data to the DIU	1 cycle
transfer the 4th 64 bits of write data to the DIU	1 cycle
Write to DRAM with locally registered write data	1 cycle
TOTAL	9 cycles

Timeslots removed to allow for read latency will also cover write latency, since the former is the larger of the two.

20.11.2 Refresh latencies

10

The number of allocated timeslots for each requester needs to take into account that a refresh must occur every 100 cycles. This can be achieved by deleting timeslots from the rotation since the number of timeslots is made programmable.

Refresh is preceded by a CPU access in the same way as any other access. This is controlled by the *CPUPreAccessTimeslots* and *CPUTotalTimeslots* configuration registers. Refresh will therefore not affect CPU performance.

As an example, in CPU pre-access mode each timeslot will last 6 cycles. If the timeslot rotation has 50 timeslots then the rotation will last 300 cycles. The refresh controller will trigger a refresh every 100 cycles. Up to 47 timeslots can be allocated to the rotation ignoring refresh. Three timeslots deleted from the 50 timeslot rotation will allow for the latency of a refresh every 100 cycles.

20.11.3 Ensuring sufficient DNC and PCU access

PCU command reads from DRAM are exceptional events and should complete in as short a time
as possible. Similarly, we must ensure there is sufficient free bandwidth for DNC accesses e.g.
when clusters of dead nozzles occur. In Table DNC is allocated 3 times average bandwidth.
PCU and DNC can also be allocated to the level 1 round-robin allocation for unused timeslots so
that unused timeslot bandwidth is preferentially available to them.

20.11.4 Basing timeslot allocation on peak bandwidths

- Since the embedded DRAM provides sufficient bandwidth to use 1:1 compression rates for the CDU and LBD, it is possible to simplify the main timeslot allocation by basing the allocation on peak bandwidths. As combined bi-level and tag bandwidth at 1:1 scaling is only 5 bits/cycle, we will usually only consider the contone scale factor as the variable in determining timeslot allocations.
- If slot allocation is based on peak bandwidth requirements then DRAM access will be *guaranteed* to all SoPEC requesters. If we do not allocate slots for peak bandwidth requirements then we can also allow for the peaks *deterministically* by adding some cycles to the print line time.
 - 20.11.5 Adjacent timeslot restrictions
 - 20.11.5.1 Non-CPU write adjacent timeslot restrictions
- Non-CPU write requestors should not be assigned adjacent timeslots as described in Section 20.7.2.3. This is because adjacent timeslots assigned to non-CPU requestors would require two sets of 256-bit write buffers and multiplexors to connect two write requestors simultaneously to the DIU. Only one 256-bit write buffer and multiplexor is implemented. Recall from section 20.7.2.3 on page 238 that if adjacent non-CPU writes are attempted, that the second write of any such pair will be disregarded and re-allocated under the unused read scheme.

20.11.5.2 Same DIU requestor adjacent timeslot restrictions

All DIU requesters have state-machines which request and transfer the read or write data before requesting again. From Figure 90 read requests have a minimum separation of 9 cycles. From Figure 92 write requests have a minimum separation of 7 cycles. Therefore adjacent timeslots

should not be assigned to a particular DIU requester because the requester will not be able to make use of all these slots.

In the case that a CPU access precedes a non-CPU access timeslots last 6 cycles so write and read requesters can only make use of every second timeslot. In the case that timeslots are not preceded by CPU accesses timeslots last 4 cycles so the same write requester can use every second timeslot but the same read requestor can use only every third timeslot. Some DIU requestors may introduce additional pipeline delays before they can request again. Therefore timeslots should be separated by more than the minimum to allow a margin.

20.11.6 Line margin

5

20

The SFU must output 1 bit/cycle to the HCU. Since *HCUNumDots* may not be a multiple of 256 bits the last 256-bit DRAM word on the line can contain extra zeros. In this case, the SFU may not be able to provide 1 bit/cycle to the HCU. This could lead to a stall by the SFU. This stall could then propagate if the margins being used by the HCU are not sufficient to hide it. The maximum stall can be estimated by the calculation: DRAM service period - X scale factor * dots used from last DRAM read for HCU line.

Similarly, if the line length is not a multiple of 256-bits then e.g. the LLU could read data from DRAM which contains padded zeros. This could lead to a stall. This stall could then propagate if the page margins cannot hide it.

A single addition of 256 cycles to the line time will suffice for all DIU requesters to mask these stalls.

20.12 EXAMPLE OUTLINE DIU PROGRAMMING

Table 121. Timeslot allocation based on peak bandwidth

Block Name	Direction	Peak Bandwidth	MainTimeslots
		which must be	allocated
		supplied	
		(bits/cycle)	
SCB	R		
	W	0.734	1
CDU	R	0.9 (SF = 6),	1 (SF = 6)
:		2 (SF = 4)	2 (SF = 4)
	W	1.8 (SF = 6), ⁸	2 (SF = 6)
		4 (SF = 4)	4 (SF = 4)
CFU	R	5.4 (SF = 6),	6 (SF = 6)
		8 (SF = 4)	8 (SF = 4)

The SCB figure of 0.734 bits/cycle applies to multi-SoPEC systems. For single-SoPEC systems, the figure is 0.050 bits/cycle.

Bandwidth for CDU(W) is *peak* value. Because of 1.5 buffering in DRAM, peak CDU(W) b/w equals 2 x average CDU(W) b/w. For CDU(R), peak b/w = average CDU(R) b/w.

LBD	R	1	1
SFU	R	2	2
	W	1	1
TE(TD)	R	1.02	1
TE(TFS)	R	0.093	0
HCU	R	0.074	0
DNC	R	2.4	3
DWU	W	6	6
LLU	R	8	8
PCU	R	1	1
TOTAL			33 (SF=6) 38 (SF=4)
			38 (SF=4)

Table 121 shows an allocation of main timeslots based on the peak bandwidths of Table

The bandwidth required for each unit is calculated allowing extra cycles for read and write circuit latency for each access requiring a bandwidth of more than 1 bit/cycle. Fractional bandwidth is supplied via unused read slots.

- 5 The timeslot rotation is 256 cycles. Timeslots are deleted from the rotation to allow for circuit latencies for accesses of up to 1 bit per cycle i.e. 1 timeslot per rotation.
 - Example 1: Scale-factor = 6

- Program the *MainTimeslot* configuration register (Table) for peak required bandwidths of SoPEC Units according to the scale factor.
- Program the read round-robin allocation to share unused read slots. Allocate PCU, DNC, HCU and TFS to level 1 read round-robin.
 - Assume scale-factor of 6 and peak bandwidths from Table .
 - Assign all DIU requestors except TE(TFS) and HCU to multiples of 1 timeslot, as indicated in Table , where each timeslot is 1 bit/cycle. This requires 33 timeslots.
- No timeslots are explicitly allocated for the fractional bandwidth requirements of TE(TFS) and HCU accesses. Instead, these units are serviced via unused read slots.
 - Allow 3 timeslots to allow for 3 refreshes in the rotation.
 - Therefore, 36 scheduled slots are used in the rotation for main timeslots and refreshes,
 some or all of which may be able to have a CPU pre-access, provided they fit in the rotation window.
 - Each of the 2 CDU(W) accesses requires 9 cycles. Per access, this implies an overhead of 1 slot (12 cycles instead of 6) in pre-access mode, or 1.25 slots (9 cycles instead of 4) for no pre-access. The cumulative overhead of the two accesses is either 2 slots (pre-access) or 3 slots (no pre-access).
- Assuming all blocks require a service guarantee of no more than a single stall across 256 bits, allow 10 cycles for read latency, which also takes care of 9-cycle write latency. This can be accounted for by reserving 2 six-cycle slots (CPU pre-access) or 3 four-cycle slots (no pre-access).

- Assume a 256 cycle timeslot rotation.
- CDU(W) and read latency reduce the number of available cycles in a rotation to: 256 2x6 2x6 = 232 cycles (CPU pre-access) or 256 3x4 3x4 = 232 cycles (no pre-access).
- As a result, 232 cycles available for 36 accesses implies each access can take 232 / 36 =
 6.44 cycles maximum. So, all accesses can have a pre-access.
- Therefore the CPU achieves a pre-access ratio of 36 / 36 = 100% of slots in the rotation.

Example 2: Scale-factor = 4

5

10

15

20

25

40

Program the *MainTimeslot* configuration register (Table) for peak required bandwidths of SoPEC Units according to the scale factor. Program the read round-robin allocation to share unused read slots. Allocate PCU, DNC, HCU and TFS to level 1 read round-robin.

- Assume scale-factor of 4 and peak bandwidths from Table .
- Assign all DIU requestors except TE(TFS) and HCU multiples of 1 timeslot, as indicated in Table , where each timeslot is 1 bit/cycle. This requires 38 timeslots.
- No timeslots are explicitly allocated for the fractional bandwidth requirements of TE(TFS)
 and HCU accesses. Instead, these units are serviced via unused read slots.
- Allow 3 timeslots to allow for 3 refreshes in the rotation.
- Therefore, 41 scheduled slots are used in the rotation for main timeslots and refreshes,
 some or all of which can have a CPU pre-access, provided they fit in the rotation window.
- Each of the 4 CDU(W) accesses requires 9 cycles. Per access, this implies an overhead of 1 slot (12 cycles instead of 6) for pre-access mode, or 1.25 slots (9 cycles instead of 4) for no pre-access. The cumulative overhead of the four accesses is either 4 slots (pre-access) or 5 slots (no pre-access).
 - Assuming all blocks require a service guarantee of no more than a single stall across 256 bits, allow 10 cycles for read latency, which also takes care of 9-cycle write latency. This can be accounted for by reserving 2 six-cycle slots (CPU pre-access) or 3 four-cycle slots (no pre-access).
 - Assume a 256 cycle timeslot rotation.
 - CDU(W) and read latency reduce the number of available cycles in a rotation to: 256 4x6 2x6 = 220 cycles (CPU pre-access) or 256 5x4 3x4 = 224 cycles (no pre-access).
- As a result, between 220 and 224 cycles are available for 41 accesses, which implies each access can take between 220 / 41 = 5.36 cycles and 224 / 41 = 5.46 cycles.
 - Work out how many slots can have a pre-access: For the lower number of 220 cycles, this implies (41 n)*6 + n*4 <= 220, where n = number of slots with no pre-access cycle. Solving the equation gives n >= 13. Check answer: 28*6 + 13*4 = 220.
- So 28 slots out of the 41 in the rotation can have CPU pre-accesses.
 - The CPU thus achieves a pre-access ratio of 28 / 41 = 68.3% of slots in the rotation.
 - 20.12.1 Slot Distributions and Stall Calculations for Individual Blocks

The following sections show how the slots for blocks with a service requirement greater than 1 bit/cycle should be distributed. Calculations are included to check that such blocks will not suffer more than one stall per rotation.

20.12.1.1 SFU

This has 2 bits/cycle on read but this is two separate channels of 1 bit/cycle sharing the same DIU interface so it is effectively 2 channels each of 1 bit/cycle so allowing the same margins as the LBD will work.

5 20.12.1.2 DWU

The DWU has 12 double buffers in each of the 6 colour planes, odd and even. These buffers are filled by the DNC and will request DIU access when double buffers fill. The DNC supplies 6 bits to the DWU every cycle (6 odd in one cycle, 6 even in the next cycle). So the service deadline is 512 cycles, given 6 accesses per 256-cycle rotation.

10 20.12.1.3 CFU

15

20

30

Here the requirement is that the DIU stall should be less than the time taken for the CFU to consume one third of its triple buffer. The total DIU stall = refresh latency + extra CDU(W) latency + read circuit latency = 3 + 5 (for 4 cycle timeslots) + 10 = 18 cycles. The CFU can consume its data at 8 bits/cycle at SF = 4. Therefore 256 bits of data will last 32 cycles so the triple buffer is safe. In fact we only need an extra 144 bits of buffering or 3×64 bits. But it is safer to have the full extra 256 bits or 4×64 bits of buffering.

20.12.1.4 LLU

The LLU has 2 channels, each of which could request at 6 bits/106 MHz channel or 4 bits/160MHz cycle, giving a total of 8 bits/160MHz cycle. The service deadline for each channel is 256 x 106 MHz cycles, i.e. all 6 colours must be transferred in 256 cycles to feed the printhead. This equates to 384 x 160 MHz cycles.

Over a span of 384 cycles, there will be 6 CDU(W) accesses, 4 refreshes and one read latency encountered at most. Assuming CPU pre-accesses for these occurrences, this means the number of available cycles is given by 384 - 6x6 - 4x6 - 10 = 314 cycles.

For a CPU pre-access slot rate of 50%, 314 cycles implies 31 CPU and 63 non-CPU accesses $(31 \times 6 + 32 \times 4 = 314)$. For 12 LLU accesses interspersed amongst these 63 non-CPU slots, implies an LLU allocation rate of approximately one slot in 5.

If the CPU pre-access is 100% across all slots, then 314 cycles gives 52 slots each to CPU and non-CPU accesses, ($52 \times 6 = 312$ cycles). Twelve accesses spread over 52 slots, implies a 1-in-4 slot allocation to the LLU.

The same LLU slot allocation rate (1 slot in 5, or 1 in 4) can be applied to programming slots across a 256-cycle rotation window. The window size does not affect the occurrence of LLU slots, so the 384-cycle service requirement will be fulfilled.

20.12.1.5 DNC

This has a 2.4 bits/cycle bandwidth requirement. Each access will see the DIU stall of 18 cycles. 2.4 bits/ cycle corresponds to an access every 106 cycles within a 256 cycle rotation. So to allow for DIU latency we need an access every 106 -18 or 88 cycles. This is a bandwidth of 2.9 bits/cycle, requiring 3 timeslots in the rotation.

20.12.1.6 CDU

The JPEG decoder produces 8 bits/cycle. Peak CDUR[ead] bandwidth is 4 bits/cycle (SF=4), peak CDUW[rite] bandwidth is 4 bits/cycle (SF=4). both with 1.5 DRAM buffering.

The CDU(R) does a DIU read every 64 cycles at scale factor 4 with 1.5 DRAM buffering. The delay in being serviced by the DIU could be read circuit latency (10) + refresh (3) + extra CDU(W) cycles (6) = 19 cycles. The JPEG decoder can consume each 256 bits of DIU-supplied data at 8 bits/cycle, i.e. in 32 cycles. If the DIU is 19 cycles late (due to latency) in supplying the read data then the JPEG decoder will have finished processing the read data 32 + 19 = 49 cycles after the DIU access. This is 64 - 49 = 15 cycles in advance of the next read. This 15 cycles is the upper limit on how much the DIU read service can further be delayed, without causing a stall. Given this margin, a stall on the read side will not occur.

On the write side, for scale factor 4, the access pattern is a DIU writes every 64 cycles with 1.5 DRAM buffereing. The JPEG decoder runs at 8 bits cycle and consumes 256 bits in 32 cycles. The CDU will not stall if the JPEG decode time (32) + DIU stall (19) < 64, which is true.

20.13 CPU DRAM ACCESS PERFORMANCE

The CPU's share of the timeslots can be specified in terms of guaranteed bandwidth and average bandwidth allocations.

The CPU's access rate to memory depends on

- the CPU read access latency i.e. the time between the CPU making a request to the DIU and receiving the read data back from the DIU.
- how often it can get access to DIU timeslots.

Table estimated the CPU read latency as 6 cycles.

How often the CPU can get access to DIU timeslots depends on the access type. This is summarised in Table 122.

Table 122. CPU DRAM access performance

Access Type Nominal CPU DRAM Notes Timeslot access rate Duration CPU Pre-CPU can access every 6 cycles Lower bound (guaranteed access bandwidth) is timeslot. 160 MHz / 6 = 26.27 MHzFractional 4 or 6 cycles Lower bound (guaranteed CPU accesses precede a CPU bandwidth) is fraction N of timeslots Pre-access (160 MHz * N / P) where N = C/T. C = CPUPreAccessTimeslots T = CPUTotalTimeslots P = (6*C + *4*(T-C)) / T*

5

In both CPU Pre-access and Fractional CPU Pre-access modes, if the CPU is not requesting the timeslots will have a duration of 3 or 4 cycles depending on whether the current access and preceding access are both to the shared read bus. This will mean that the timeslot rotation will run faster and more bandwidth is available.

If the CPU runs out of its instruction cache then instruction fetch performance is only limited by the on-chip bus protocol. If data resides in the data cache then 160 MHz performance is achieved. Accessing memory mapped registers, PSS or ROM with a 3 cycle bus protocol (address cycle + data cycle) gives 53 MHz performance.

Due to the action of CPU caching, some bandwidth limiting of the CPU in Fractional CPU Preaccess mode is expected to have little or no impact on the overall CPU performance.

20.14 IMPLEMENTATION

The DRAM Interface Unit (DIU) is partitioned into 2 logical blocks to facilitate design and verification.

- a. The DRAM Arbitration Unit (DAU) which interfaces with the SoPEC DIU requesters.
- b. The DRAM Controller Unit (DCU) which accesses the embedded DRAM.

The basic principle in design of the DIU is to ensure that the eDRAM is accessed at its maximum rate while keeping the CPU read access latency as low as possible.

The DCU is designed to interface with single bank 20 Mbit IBM Cu-11 embedded DRAM performing random accesses every 3 cycles. Page mode burst of 4 write accesses, associated with the CDU, are also supported.

The DAU is designed to support interleaved accesses allowing the DRAM to be accessed every 3 cycles where back-to-back accesses do not occur over the shared 64-bit read data bus.

20.14.1 DIU Partition

20

20.14.2 Definition of DCU IO

25 Table 123. DCU interface

Port Name	Pins	1/0	Description	
Clocks and Resets		!		
pclk	1	ln	SoPEC Functional clock	
dau_dcu_reset_n	1	ln	Active-low, synchronous reset in <i>pclk</i> domain. Incorporates DAU hard and soft resets.	
Inputs from DAU		1		
dau_dcu_msn2stall	1	ln	Signal indicating from DAU Arbitration Logic which when asserted stalls DCU in <i>MSN2</i> state.	
dau_dcu_adr[21:5]	17	ln	Signal indicating the address for the DRAM access. This is a 256-bit aligned DRAM address.	
dau_dcu_rwn	1	ln	Signal indicating the direction for the DRAM	

			access (1=read, 0=write).
dau_dcu_cduwpage	1	In	Signal indicating if access is a CDU write
			page mode access (1=CDU page mode,
			0=not CDU page mode).
dau_dcu_refresh	1	ln	Signal indicating that a refresh command is to
			be issued. If asserted dau_dcu_adr,
			dau_dcu_rwn and dau_dcu_cduwpage are
·			ignored.
dau_dcu_wdata	256	In	256-bit write data to DCU
dau_dcu_wmask	32	ln	Byte encoded write data mask for 256-bit
			dau_dcu_wdata to DCU
			Polarity : A "1" in a bit field of
			dau_dcu_wmask means that the
			corresponding byte in the 256-bit
			dau_dcu_wdata <u>is</u> written to DRAM.
Outputs to DAU		.,	
dcu_dau_adv	1	Out	Signal indicating to DAU to supply next
			command to DCU
dcu_dau_wadv	1	Out	Signal indicating to DAU to initiate next non-
			CPU write
dcu_dau_refreshcompl	1	Out	Signal indicating that the DCU has completed
ete			a refresh.
dcu_dau_rdata	256	Out	256-bit read data from DCU.
dcu_dau_rvalid	1	Out	Signal indicating valid read data on
			dcu_dau_rdata.
			T .

20.14.3 DRAM access types

The DRAM access types used in SoPEC are summarised in Table 124. For a refresh operation the DRAM generates the address internally.

Table 124. SoPEC DRAM access types

Туре	Access
Read	Random 256-bit read
Write	Random 256-bit write with byte write masking
	Page mode write for burst of 4 256-bit words with byte write masking
Refresh	Single refresh

20.14.4 Constructing the 20 Mbit DRAM from two 10 Mbit instances

The 20 Mbit DRAM is constructed from two 10 Mbit instances. The address ranges of the two instances are shown in Table 125.

Table 125. Address ranges of the two 10 Mbit instances in the 20 Mbit DRAM

Instance	Address	Hex 256-bit word address	Binary 256-bit word address
Instance0	First word in lower 10 Mbit	00000	0 0000 0000 0000 0000
Instance0	Last word in lower 10 Mbit	09FFF	0 1001 1111 1111 1111
Instance1	First word in upper 10 Mbit	0A000	0 1010 0000 0000 0000
Instance1	Last word in upper 10 Mbit	13FFF	1 0011 1111 1111 1111

There are separate macro select signals, *inst0_MSN* and *inst1_MSN*, for each instance and separate dataout busses *inst0_DO* and *inst1_DO*, which are multiplexed in the DCU. Apart from these signals both instances share the DRAM output pins of the DCU.

The DRAM Arbitration Unit (DAU) generates a 17 bit address, <code>dau_dcu_adr[21:5]</code>, sufficient to address all 256-bit words in the 20 Mbit DRAM. The upper 5 bits are used to select between the two memory instances by gating their MSN pins. If instance1 is selected then the lower 16-bits are translated to map into the 10 Mbit range of that instance. The multiplexing and address translation rules are shown in Table 126.

In the case that the DAU issues a refresh, indicated by $dau_dcu_refresh$, then both macros are selected. The other control signals

Table 126. Instance selection and address translation

15

10

dau_dcu_refresh	DAU Address	Instance	inst0_MSN	inst1_MSN	Address translation
	bits	selected			
	dau_dcu_adr[21:17]			:	
0	< 01010	Instance0	MSN	1	A[15:0] =
					dau_dcu_adr[20:5]
	>= 01010	Instance1	1	MSN	A[15:0] =
					dau_dcu_adr[21:5]
					- hA000
1	-	Instance0	MSN	MSN	-
		and			
		Instance1			

dau_dcu_adr[21:5], dau_dcu_rwn and dau_dcu_cduwpage are ignored.

The instance selection and address translation logic is shown in Figure 102.

The address translation and instance decode logic also increments the address presented to the DRAM in the case of a page mode write. Pseudo code is given below.

if rising_edge(dau_dcu_valid) then

```
//capture the address from the DAU
                           next cmdadr[21:5] = dau_dcu_adr[21:5]
                        elsif pagemode_adr_inc == 1 then
                           //increment the address
 5
                           next\_cmdadr[21:5] = cmdadr[21:5] + 1
                        else
                           next cmdadr[21:5] = cmdadr[21:5]
                        if rising edge(dau dcu valid) then
10
                           //capture the address from the DAU
                           adr_var[21:5]:= dau_dcu_adr[21:5]
                           adr_var[21:5]:= cmdadr[21:5]
15
                        if adr_var[21:17] < 01010 then
                           //choose instance0
                           instance sel = 0
                           A[15:0] = adr_var[20:5]
                        else
20
                           //choose instance1
                           instance sel = 1
                              A[15:0] = adr var[21:5] - hA000
                   Pseudo code for the select logic, SEL0, for DRAM Instance0 is given below.
25
                        //instance0 selected or refresh
                        if instance sel == 0 OR dau dcu refresh == 1 then
                           inst0 MSN = MSN
                        else
                           inst0 MSN = 1
30
                   Pseudo code for the select logic, SEL1, for DRAM Instance1 is given below.
                         //instancel selected or refresh
                         if instance sel == 1 OR dau dcu refresh == 1 then
                           inst1 MSN = MSN
                        else
35
                           inst1 MSN = 1
      During a random read, the read data is returned, on dcu_dau_rdata, after time Tacc, the random
      access time, which varies between 3 and 8 ns (see Table ). To avoid any metastability issues
      the read data must be captured by a flip-flop which is enabled 2 pclk cycles or 12.5 ns after the
      DRAM access has been started. The DCU generates the enable signal dcu_dau_rvalid to capture
40
      dcu dau rdata.
      The byte write mask dau_dcu_wmask[31:0] must be expanded to the bit write mask
      bitwritemask[255:0] needed by the DRAM.
```

20.14.5 DAU-DCU interface description

The DCU generates a second signal, dcu_dau_wadv, which is asserted in the RST state. This indicates to the DAU that it can perform arbitration in advance for non-CPU writes. The reason for performing arbitration in advance for non-CPU writes is explained in "Command Multiplexor Sub-block

Table 136. Command Multiplexor Sub-block IO Definition

write_data_accept	2	Out	Signal indicating the Command Multiplexor has accepted
			the write data from the write multiplexor
			00=not valid
			01=accepts CPU write data
			10=accepts non-CPU write data
			11=not valid
Inputs from DCU			
dcu_dau_adv	1	ln	Signal indicating to DAU to supply next command to DCU

dcu_dau_wadv	1	In	Signal indicating to DAU to initiate next non-CPU write
Outputs to DCU	t		
dau_dcu_adr[21:5]	17	Out	Signal indicating the address for the DRAM access. This is
			a 256-bit aligned DRAM address.
dau_dcu_rwn	1	Out	Signal indicating the direction for the DRAM access
			(1=read, 0=write).
dau_dcu_cduwpage	1	Out	Signal indicating if access is a CDU write page mode
			access (1=CDU page mode, 0=not CDU page mode).
dau_dcu_refresh	1	Out	Signal indicating that a refresh command is to be issued. If
			asserted dau_dcu_adr, dau_dcu_rwn and
•			dau_dcu_cduwpage are ignored.
dau_dcu_wdata	256	Out	256-bit write data to DCU
dau_dcu_wmask	32	Out	Byte encoded write data mask for 256-bit dau_dcu_wdata
			to DCU

The DCU state-machine can stall in the MSN2 state when the signal dau_dcu_msn2stall is asserted by the DAU Arbitration Logic,

The states of the DCU state-machine are summarised in Table. 127.

Table 127. States of the DCU state-machine

State	Description
RST	Restore state
MSN1	Macro select state 1
MSN2	Macro select state 2

20.14.6 DCU state machines

5

The IBM DRAM has a simple SRAM like interface. The DRAM is accessed as a single bank. The state machine to access the DRAM is shown in Figure 104.

The signal pagemode_adr_inc is exported from the DCU as dcu_dau_cduwaccept.

dcu_dau_cduwaccept tells the DAU to supply the next write data to the DRAM

20.14.7 CU-11 DRAM timing diagrams

The IBM Cu-11 embedded DRAM datasheet is referenced as [16].

Table 128 shows the timing parameters which must be obeyed for the IBM embedded DRAM.

Table 128. 1.5 V Cu-11 DRAM a.c. parameters

Symbol	Parameter	Min	Max	Units
T _{set}	Input setup to MSN/PGN	1	 	ns
T _{hid}	Input hold to MSN/PGN	2	-	ns
T _{acc}	Random access time	3	8	ns

T _{act}	MSN active time	8	100k	ns
T _{res}	MSN restore time	4	-	ns
T _{cyc}	Random R/W cycle time	12	-	ns
T _{rfc}	Refresh cycle time	12	-	ns
T _{accp}	Page mode access time	1	3.9	ns
T _{pa}	PGN active time	1.6	-	ns
T_{pr}	PGN restore time	1.6	-	ns
T _{pcyc}	PGN cycle time	4	-	ns
T _{mprd}	MSN to PGN restore delay	6	-	ns
T _{actp}	MSN active for page mode	12	-	ns
T _{ref}	Refresh period	-	3.2	ms
T _{pamr}	Page active to MSN restore	4		ns

The IBM DRAM is asynchronous. In SoPEC it interfaces to signals clocked on *pclk*. The following timing diagrams show how the timing parameters in Table 129 are satisfied in SoPEC.

20.14.8 Definition of DAU IO

Table 129. DAU interface

Port Name	Pins	1/0	Description
Clocks and Resets			
pclk	1	ln	SoPEC Functional clock
prst_n	1	ln	Active-low, synchronous reset in pclk domain
dau_dcu_reset_n	1	Out	Active-low, synchronous reset in pclk domain. This
	:		reset signal, exported to the DCU, incorporates the
			locally captured DAU version of hard reset (prst_n) and
			the soft reset configuration register bit "Reset".
CPU Interface	L	1	
cpu_adr	22	In	CPU address bus for both DRAM and configuration
	:		register access.
		i	9 bits (bits 10:2) are required to decode the
			configuration register address space.
			22 bits can address the DRAM at byte level. DRAM
			addresses cannot cross a 256-bit word DRAM
			boundary.
cpu_dataout	32	In	Shared write data bus from the CPU for DRAM and ·
		.	configuration data
diu_cpu_data	32	Out	Configuration, status and debug read data bus to the
			СРИ
diu_cpu_debug_valid	1	Out	Signal indicating the data on the diu_cpu_data bus is
			valid debug data.

cpu_rwn	1	ln	Common read/not-write signal from the CPU
cpu_acode	2	ln	CPU access code signals.
			cpu_acode[0] - Program (0) / Data (1) access
			cpu_acode[1] - User (0) / Supervisor (1) access
		1	The DAU will only allow supervisor mode accesses to
			data space.
cpu_diu_sel	1	ln	Block select from the CPU. When cpu_diu_sel is high
			both <i>cpu_adr</i> and <i>cpu_dataout</i> are valid
diu_cpu_rdy	1	Out	Ready signal to the CPU. When diu_cpu_rdy is high it
			indicates the last cycle of the access. For a write cycle
			this means <i>cpu_dataout</i> has been registered by the
			block and for a read cycle this means the data on
			diu_cpu_data is valid.
diu_cpu_berr	1	Out	Bus error signal to the CPU indicating an invalid
			access.
DIU Read Interface to SoF	EC U	nits	
<unit>_diu_rreq</unit>	1	In	SoPEC unit requests DRAM read. A read request must
			be accompanied by a valid read address.
<unit>_diu_radr[21:5]</unit>	17	In	Read address to DIU
			17 bits wide (256-bit aligned word).
			Note : " <unit>" refers to non-CPU requesters only.</unit>
			CPU addresses are provided via "cpu_adr".
diu_ <unit>_rack</unit>	1	Out	Acknowledge from DIU that read request has been
			accepted and new read address can be placed on
			<unit>_diu_radr</unit>
diu_data	64	Out	Data from DIU to SoPEC Units except CPU.
			First 64-bits is bits 63:0 of 256 bit word
			Second 64-bits is bits 127:64 of 256 bit word
			Third 64-bits is bits 191:128 of 256 bit word
			Fourth 64-bits is bits 255:192 of 256 bit word
dram_cpu_data	256	Out	256-bit data from DRAM to CPU.
diu_ <unit>_rvalid</unit>	1	Out	Signal from DIU telling SoPEC Unit that valid read data
			is on the <i>diu_data</i> bus
DIU Write Interface to SoF	EC U	nits	-
<unit>_diu_wreq</unit>	1	In	SoPEC unit requests DRAM write. A write request
			must be accompanied by a valid write address.
			Note : " <unit>" refers to non-CPU requesters only.</unit>
<unit>_diu_wadr[21:5]</unit>	17	In	Write address to DIU except CPU, CDU
	.	-	17 bits wide (256-bit aligned word)
		<u> </u>	

	Т		Note : " <unit>" refers to non-CPU requesters,</unit>
			excluding the CDU.
scb_diu_wmask[7:0]	8	ln	Byte write enables applicable to a given 64-bit quarter-
			word transferred from the SCB. Note that different
			mask values are used with each quarter-word.
			Requirement for the USB host core.
diu_cpu_write_rdy	1	Out	Flag indicating that the CPU posted write buffer is
did_cpd_write_rdy	'	Out	empty.
cpu_diu_wdatavalid	1	In	Write enable for the CPU posted write buffer. Also
opu_did_wdatavalid	'	"'	confirms that the CPU write data, address and mask
			are valid.
cpu_diu_wdata	128	ln	CPU write data which is loaded into the posted write
cpu_diu_wdata	120	""	buffer.
anu diu wadel04.41	18	1	
cpu_diu_wadr[21:4]		ln	128-bit aligned CPU write address.
cpu_diu_wmask[15:0]	16	ln	Byte enables for 128-bit CPU posted write.
cdu_diu_wadr[21:3]	19	ln	CDU Write address to DIU
			19 bits wide (64-bit aligned word)
			Addresses cannot cross a 256-bit word DRAM
			boundary.
diu_ <unit>_wack</unit>	1	Out	Acknowledge from DIU that write request has been
			accepted and new write address can be placed on
	<u> </u>	ļ	<unit>_diu_wadr</unit>
<unit>_diu_data[63:0]</unit>	64	ln	Data from SoPEC Unit to DIU except CPU.
			First 64-bits is bits 63:0 of 256 bit word
			Second 64-bits is bits 127:64 of 256 bit word
			Third 64-bits is bits 191:128 of 256 bit word
			Fourth 64-bits is bits 255:192 of 256 bit word
			Note : " <unit>" refers to non-CPU requesters only.</unit>
<unit>_diu_wvalid</unit>	1	ln	Signal from SoPEC Unit indicating that data on
			<unit>_diu_data is valid.</unit>
			Note : " <unit>" refers to non-CPU requesters only.</unit>
Outputs to DCU			
dau_dcu_msn2stall	1	Out	Signal indicating from DAU Arbitration Logic which
			when de-asserted stalls DCU in MSN2 state.
dau_dcu_adr[21:5]	17	Out	Signal indicating the address for the DRAM access.
			This is a 256-bit aligned DRAM address.
dau_dcu_rwn	1	Out	Signal indicating the direction for the DRAM access
			(1=read, 0=write).
dau_dcu_cduwpage	1	Out	Signal indicating if access is a CDU write page mode
<u> </u>			

			access (1=CDU page mode, 0=not CDU page mode).
dau_dcu_refresh	1	Out	Signal indicating that a refresh command is to be issued. If asserted dau_dcu_cmd_adr, dau_dcu_rwn and dau_dcu_cduwpage are ignored.
dau_dcu_wdata	256	Out	256-bit write data to DCU
dau_dcu_wmask	32	Out	Byte-encoded write data mask for 256-bit dau_dcu_wdata to DCU Polarity: A "1" in a bit field of dau_dcu_wmask means that the corresponding byte in the 256-bit dau_dcu_wdata is written to DRAM.
Inputs from DCU	.	<u> </u>	
dcu_dau_adv	1	ln	Signal indicating to DAU to supply next command to DCU
dcu_dau_wadv	1	In	Signal indicating to DAU to initiate next non-CPU write
dcu_dau_refreshcomplete	1	In	Signal indicating that the DCU has completed a refresh.
dcu_dau_rdata	256	In	256-bit read data from DCU.
dcu_dau_rvalid	1	In	Signal indicating valid read data on dcu_dau_rdata.

The CPU subsystem bus interface is described in more detail in Section 11.4.3. The DAU block will only allow supervisor-mode accesses to update its configuration registers (i.e. $cpu_acode[1:0]$ = b11). All other accesses will result in diu_cpu_berr being asserted.

20.14.9 DAU Configuration Registers

Table 130. DAU configuration registers

Address (DIU_base +)	Register	#bits	Reset	Description
Reset				
0x00	Reset	1	0x1	A write to this register causes a reset of the DIU. This register can be read to indicate the reset state: 0 - reset in progress 1 - reset not in progress
Refresh	.			
0x04	RefreshPeriod	9	0x063	Refresh controller. When set to 0 refresh is off, otherwise the value indicates the number of cycles, less one, between each

	<u> </u>			refresh. [Note that for a system clock
				frequency of 160MHz, a value
				exceeding 0x63 (indicating a 100-cycle
				refresh period) should not be
				programmed, or the DRAM will
				malfunction.]
	ation and control		_	
0x08	NumMainTimeslots	6	0x01	Number of main timeslots (1-64) less
				one
0x0C	CPUPreAccessTime	4	0x0	(CPUPreAccessTimeslots + 1) main
	s lots			slots out of a total of
				(CPUTotalTimeslots + 1) are pre
				ceded by a CPU access.
0x10	CPUTotalTimeslots	4	0x0	(CPUPreAccessTimeslots + 1) main
				slots out of a total of
				(CPUTotalTimeslots + 1) are pre
				ceded by a CPU access.
0x100-0x1FC	MainTimeslot[63:0]	64x4	[63:1][3:0]	Programmable main timeslots (up to
			= 0x0	64 main timeslots).
			[0][3:0]	·
			= 0xE	
0×200	ReadRoundRobinLe	12	0x000	For each read requester plus refresh
	vel			0 = level1 of round-robin
				1 = level2 of round-robin
				The bit order is defined in Table .
0x204	EnableCPURound	1	0x1	Allows the CPU to participate in the
	Robin			unused read round-robin scheme. If
				disabled, the shared CPU/refresh
				round-robin position is dedicated
				solely to refresh.
0x208	RotationSync	1	0x1	Writing 0, followed by 1 to this bit
			OX.	allows the timeslot rotation to advance
				on a cycle basis which can be
				determined by the CPU.
0x20C	minNonCPUReadAd	12	0x800	12 MSBs of lowest DRAM address
	r		3,000	which may be read by non-CPU
	[
0.210		40	0000	requesters.
0x210	minDWUWriteAdr	12	0x800	12 MSBs of lowest DRAM address
				which may be written to by the DWU.

0x214	minNonCPUWriteAd	12	0x800	12 MSBs of lowest DRAM address
	r			which may be written to by non-CPU
				requesters other than the DWU.
Debug	<u> </u>	<u> </u>	<u> </u>	
0x300	DebugSelect[11:2]	10	0x304	Debug address select. Indicates the
				address of the register to report on the
				diu_cpu_data bus when it is not
				otherwise being used.
				When this signal carries debug
				information the signal
		:		diu_cpu_debug_valid will be asserted.

5 20.14.9.1 Configuration register reset state

The *RefreshPeriod* configuration register has a reset value of 0x063 which ensures that a refresh will occur every 100 cycles and the contents of the DRAM will remain valid.

The CPUPreAccessTimeslots and CPUTotalTimeslots configuration registers both have a reset value of 0x0. Matching values in these two registers means that every slot has a CPU pre-acess. NumMainTimeslots is reset to 0x1, so there are just 2 main timeslots in the rotation initially. These slots alternate between SCB writes and PCU reads, as defined by the reset value of

5 *MainTimeslot*[63:0], thus respecting at reset time the general rule that adjacent non-CPU writes are not permitted.

The first access issued by the DIU after reset will be a refresh.

20.14.9.2 DIU Debug

10

20

External visibility of the DIU must be provided for debug purposes. To facilitate this debug registers are added to the DIU address space.

The DIU CPU system data bus $diu_cpu_data[31:0]$ returns configuration and status register information to the CPU. When a configuration or status register is not being read by the CPU debug data is returned on $diu_cpu_data[31:0]$ instead. An accompanying active high $diu_cpu_debug_valid$ signal is used to indicate when the data bus contains valid debug data.

The DIU features a *DebugSelect* register that controls a local multiplexor to determine which register is output on *diu_cpu_data[31:0]*.

Three kinds of debug information are gathered:

a. The order and access type of DIU requesters winning arbitration.

This information can be obtained by observing the signals in the *ArbitrationHistory* debug register at *DIU_Base+0x304* described in Table 133.

Table 133. ArbitrationHistory debug register description, DIU_base+0x304

Field name	Bits	Description
arb_gnt	1	Signal lasting 1 cycle which is asserted in the cycle following a main
		arbitration or pre-arbitration.
arb_executed	1	Signal lasting 1 cycle which indicates that an arbitration result has
		actually been executed. Is used to differentiate between *pre*-arbitration
		and *main* arbitration, both of which cause arb_gnt to be asserted. If
		arb_executed and arb_gnt are both high, then a main (executed)
		arbitration is indicated.
arb_sel	5	Signal indicating which requesting SoPEC Unit has won arbitration.
		Encoding is described in Table . Refresh winning arbitration is
		indicated by access_type.
timeslot_number	6	Signal indicating which main timeslot is either currently being serviced,
		or about to be serviced. The latter case applies where a main slot is pre-
		empted by a CPU pre-access or a scheduled refresh.
access_type	3	Signal indicating the origin of the winning arbitration
		000 = Standard CPU pre-access.
		001 = Scheduled refresh.

		010 = Standard non-CPU timeslot.
		011 = CPU access via unused read/write slot, re-allocated by round
		robin.
		100 = Non-CPU write via unused write slot, re-allocated at pre-
		arbitration.
		101 = Non-CPU read via unused read/write slot, re-allocated by round
		robin.
		110 = Refresh via unused read/write slot, re-allocated by round robin.
		111 = CPU / Refresh access due to <i>RotationSync</i> = 0.
back2back_non_c	1	Instantaneous indicator of attempted illegal back-to-back non-CPU
pu_write		write. (Recall from section 20.7.2.3 on page 212 that the second write of
		any such pair is disregarded and re-allocated via the unused read
		round-robin scheme.)
sticky_back2back_	1	Sticky version of same, cleared on reset.
non_cpu_write		
rotation_sync	1	Current value of the <i>RotationSync</i> configuration bit.
rotation_state	2	These bits indicate the current status of pre-arbitation and main timeslot
		rotation, as a result of the <i>RotationSync</i> setting.
		00 = Pre-arb enabled, rotation enabled.
		01 = Pre-arb disabled, rotation enabled.
		10 = Pre-arb disabled, rotation disabled.
		11 = Pre-arb enabled, rotation disabled.
		00 is the normal functional setting when <i>RotationSync</i> is 1.
		01 indicates that pre-arbitration has halted at the end of its rotation
		because of RotationSync having been cleared. However the main
		arbitration has yet to finish its current rotation.
		10 indicates that both pre-arb and the main rotation have halted, due to
		RotationSync being 0 and that only CPU accesses and refreshes are
		allowed.
		11 indicates that <i>RotationSync</i> has just been changed from 0 to 1 and
	1	that pre-arbitration is being given a head start to look ahead for non-
		CPU writes, in advance of the main rotation starting up again.
sticky_invalid_non	1	Sticky bit to indicate an attempted non-CPU access with an invalid
_cpu_adr		address. Cleared by reset or by an explicit write by the CPU.
T-11-404		road soland write solanceding

The encoding for arb_sel is described in Table 134.

b. The time between a DIU requester requesting an access and completing the access. This information can be obtained by observing the signals in the *DIUPerformance* debug register at *DIU_Base+0x308* described in Table 135. The encoding for *read_sel* and *write_sel* is described in Table . The data collected from *DIUPerformance* can be post-processed to count the number of cycles between a unit requesting DIU access and the access being completed.

Table 135. DIUPerformance debug register description, DIU_base+0x308

10

Field name	Bits	Description
<unit>_diu_rreq</unit>	12	Signal indicating that SoPEC unit requests DRAM read.
<unit>_diu_wreq</unit>	5	Signal indicating that SoPEC unit requests DRAM write.
refresh_req	1	Signal indicating that refresh has requested a DIU access.
read_sel[4:0]	5	Signal indicating the SoPEC Unit for which the current read

		transaction is occurring. Encoding is described in Table .
read_complete	i	Signal indicating that read transaction to SoPEC Unit indicated by read_sel is complete i.e. that the last read data has been output by the DIU.
write_sel[4:0]		Signal indicating the SoPEC Unit for which the current write transaction is occurring. Encoding is described in Table .
write_complete		Signal indicating that write transaction to SoPEC Unit indicated by write_sel is complete i.e. that the last write data has been transferred to the DIU.
dcu_refresh_complete	1	Signal indicating that <i>refresh</i> has completed.

c.Interface signals to DIU requestors and DAU-DCU interface.

All interface signals with the exception of data busses at the interfaces between the DAU and DCU and DIU write and requestors can be monitored in debug mode by observing debug registers DIU_Base+0x314 to DIU_Base+0x354.

5 20.14.10 DRAM Arbitration Unit (DAU)

The DAU is shown in Figure 101.

The DAU is composed of the following sub-blocks

- a. CPU Configuration and Arbitration Logic sub-block.
- b. Command Multiplexor sub-block.

15

10 c. Read and Write Data Multiplexor sub-block.

The function of the DAU is to supply DRAM commands to the DCU.

- The DCU requests a command from the DAU by asserting dcu_dau_adv.
- The DAU Command Multiplexor requests the Arbitration Logic sub-block to arbitrate the
 next DRAM access. The Command Multiplexor passes dcu_dau_adv as the re_arbitrate
 signal to the Arbitration Logic sub-block.
- If the *RotationSync* bit has been cleared, then the arbitration logic grants exclusive access to the CPU and scheduled refreshes. If the bit has been set, regular arbitration occurs. A detailed description of *RotationSync* is given in section 20.14.12.2.1 on page 295.
- Until the Arbitration Logic has a valid result it stalls the DCU by asserting
 dau_dcu_msn2stall. The Arbitration Logic then returns the selected arbitration winner to the Command Multiplexor which issues the command to the DRAM. The Arbitration Logic could stall for example if it selected a shared read bus access but the Read Multiplexor indicated it was busy by de-asserting read_cmd_rdy[1].
- In the case of a read command the read data from the DRAM is multiplexed back to the
 read requestor by the Read Multiplexor. In the case of a write operation the Write
 Multiplexor multiplexes the write data from the selected DIU write requestor to the DCU
 before the write command can occur. If the write data is not available then the Command
 Multiplexor will keep dau_dcu_valid de-asserted. This will stall the DCU until the write
 command is ready to be issued.

Arbitration for non-CPU writes occurs in advance. The DCU provides a signal dcu_dau_wadv which the Command Multiplexor issues to the Arbitrate Logic as re_arbitrate_wadv. If arbitration is blocked by the Write Multiplexor being busy, as indicated by write_cmd_rdy[1] being de-asserted, then the Arbitration Logic will stall the DCU by asserting dau_dcu_msn2stall until the Write Multiplexor is ready.

20.14.10.1 Read Accesses

The timing of a non-CPU DIU read access are shown in Figure 109. Note *re_arbitrate* is asserted in the *MSN2* state of the previous access.

Note the *fixed* timing relationship between the read acknowledgment and the first rvalid for all non-CPU reads. This means that the second and any later reads in a back-to-back non-CPU sequence have their acknowledgments asserted one cycle later, i.e. in the "MSN1" DCU state. The timing of a CPU DIU read access is shown in Figure 110. Note *re_arbitrate* is asserted in the *MSN2* state of the previous access.

Some points can be noted from Figure 109 and Figure 110.

15 DIU requests:

5

30

35

- For non-CPU accesses the <unit>_diu_rreq signals are registered before the arbitration can
- For CPU accesses the cpu_diu_rreq signal is not registered to reduce CPU DIU access latency.
- Arbitration occurs when the *dcu_dau_adv* signal from the DCU is asserted. The DRAM address for the arbitration winner is available in the next cycle, the *RST* state of the DCU.

The DRAM access starts in the *MSN1* state of the DCU and completes in the *RST* state of the DCU.

Read data is available:

- In the MSN2 cycle where it is output unregistered to the CPU
 - In the MSN2 cycle and registered in the DAU before being output in the next cycle to all other read requestors in order to ease timing.

The DIU protocol is in fact:

- Pipelined i.e. the following transaction is initiated while the previous transfer is in progress.
- Split transaction i.e. the transaction is split into independent address and data transfers. Some general points should be noted in the case of CPU accesses:
- Since the CPU request is not registered in the DIU before arbitration, then the CPU must generate the request, route it to the DAU and complete arbitration all in 1 cycle. To facilitate this CPU access is arbitrated late in the arbitration cycle (see Section 20.14.12.2).
- Since the CPU read data is not registered in the DAU and CPU read data is available 8 ns
 after the start of the access then 4.5 ns are available for routing and any shallow logic
 before the CPU read data is captured by the CPU (see Section 20.14.4).

The phases of CPU DIU read access are shown in Figure 111. This matches the timing shown in 40 Table 135.

20.14.10.2 Write Accesses

CPU writes are posted into a 1-deep write buffer in the DIU and written to DRAM as shown below in Figure 112.

The sequence of events is as follows:-

- [1] The DIU signals that its buffer for CPU posted writes is empty (and has been for some time in the case shown).
 - [2] The CPU asserts "cpu_diu_wdatavalid" to enable a write to the DIU buffer and presents valid address, data and write mask. The CPU considers the write posted and thus complete in the cycle following [2] in the diagram below.
- [3] The DIU stores the address/data/mask in its buffer and indicates to the arbitration logic that a posted write wishes to participate in any upcoming arbitration.
 - [4] Provided the CPU still has a pre-access entitlement left, or is next in line for a round-robin award, a slot is arbitrated in favour of the posted write. Note that posted CPU writes have higher arbitration priority than simultaneous CPU reads.
- 15 [5] The DRAM write occurs.
 - [6] The earliest that "diu_cpu_write_rdy" can be re-asserted in the "MSN1" state of the DRAM write. In the same cycle, having seen the re-assertion, the CPU can asynchronously turn around "cpu_diu_wdatavalid" and enable a subsequent posted write, should it wish to do so. The timing of a non-CPU/non-CDU DIU write access is shown below in Figure 113.
- Compared to a read access, write data is only available from the requester 4 cycles after the address. An extra cycle is used to ensure that data is first registered in the DAU, before being despatched to DRAM. As a result, writes are pre-arbitrated 5 cycles in advance of the main arbitration decision to actually write the data to memory.

The diagram above shows the following sequence of events :-

- [1] A non-CPU block signals a write request.
 - [2] A registered version of this is available to the DAU arbitration logic.
 - [3] Write pre-arbitration occurs in favour of the requester.
 - [4] A write acknowledgment is returned by the DIU.
- [5] The pre-arbitration will only be upheld if the requester supplies 4 consecutive write data quarter-words, qualified by an asserted wvalid flag.
 - [6] Provided this has happened, the main arbitration logic is in a position at [6] to reconfirm the pre-arbitration decision. Note however that such reconfirmation may have to wait a further one or two DRAM accesses, if the write is pre-empted by a CPU pre-access and/or a scheduled refresh.
- [7] This is the earliest that the write to DRAM can occur.
 - Note that neither the arbitration at [8] nor the pre-arbitration at [9] can award its respective slot to a non-CPU write, due to the ban on back-to-back accesses.

The timing of a CDU DIU write access is shown overleaf in Figure 114.

This is simular to a regular non-CPU write access, but uses page mode to carry out 4 consecutive DRAM writes to contiguous addresses. As a consequence, subsequent accesses are delayed by

6 cycles, as shown in the diagram. Note that a new write can be pre-arbitrated at [10] in Figure 114.

20.14.11 Command Multiplexor Sub-block

20.14.11.1 Command Multiplexor Sub-block Description

The Command Multiplexor sub-block issues read, write or refresh commands to the DCU, according to the SoPEC Unit selected for DRAM access by the Arbitration Logic. The Command Multiplexor signals the Arbitration Logic to perform arbitration to select the next SoPEC Unit for DRAM access. It does this by asserting the *re_arbitrate* signal. *re_arbitrate* is asserted when the DCU indicates on *dcu_dau_adv* that it needs the next command.

The Command Multiplexor is shown in Figure 115.

Initially, the issuing of commands is described. Then the additional complexity of handling non-CPU write commands arbitrated in advance is introduced.

10 DAU-DCU interface

5

15

20

See Section 20.14.5 for a description of the DAU-DCU interface.

Generating re_arbitrate

The condition for asserting *re_arbitrate* is that the DCU is looking for another command from the DAU. This is indicated by *dcu_dau_adv* being asserted.

re_arbitrate = dcu_dau_adv

Interface to SoPEC DIU requestors

When the Command Multiplexor initiates arbitration by asserting *re_arbitrate* to the Arbitration Logic sub-block, the arbitration winner is indicated by the *arb_sel[4:0]* and *dir_sel[1:0]* signals returned from the Arbitration Logic. The validity of these signals is indicated by *arb_gnt*. The encoding of *arb_sel[4:0]* is shown in Table

The value of *arb_sel[4:0]* is used to control the *steering multiplexor* to select the DIU address of the winning arbitration requestor. The *arb_gnt* signal is decoded as an acknowledge,

diu_<unit>_*ack back to the winning DIU requestor. The timing of these operations is shown in Figure 116. adr[21:0] is the output of the steering multiplexor controlled by arb_sel[4:0]. The steering multiplexor can acknowledge DIU requestors in successive cycles.

Command Issuing Logic

The address presented by the winning SoPEC requestor from the steering multiplexor is presented to the command issuing logic together with arb_sel[4:0] and dir_sel[1:0].

The command issuing logic translates the winning command into the signals required by the DCU. adr_[21:0], arb_sel[4:0] and dir_sel[1:0] comes from the steering multiplexor.

```
dau_dcu_rwn = (dir_sel[1:0] == read)
dau_dcu_cduwpage = (arb_sel[4:0] == CDU write)
dau dcu refresh = (dir sel[1:0] == refresh)
```

5 dau_dcu_valid indicates that a valid command is available to the DCU.

For a write command, dau_dcu_valid will not be asserted until there is also valid write data present. This is indicated by the signal $write_data_valid[1:0]$ from the Read Write Data Multiplexor sub-block.

For a write command, the data issued to the DCU on dau_dcu_wdata[255:0] is multiplexed from cpu_wdata[31:0] and wdata[255:0] depending on whether the write is a CPU or non-CPU write. The write data from the Write Multiplexor for the CDU is available on wdata[63:0]. This data must be issued to the DCU on dau_dcu_wdata[255:0]. wdata[63:0] is copied to each 64-bit word of dau_dcu_wdata[255:0].

CPU write masking

The CPU write data bus is only 128 bits wide. $cpu_diu_wmask[15:0]$ indicates how many bytes of that 128 bits should be written. The associated address $cpu_diu_wadr[21:4]$ is a 128-bit aligned address. The actual DRAM write must be a 256-bit access. The command multiplexor issues the 256-bit DRAM address to the DCU on $dau_dcu_adr[21:5]$. $cpu_diu_wadr[4]$ and $cpu_diu_wmask[15:0]$ are used jointly to construct a byte write mask $dau_dcu_wmask[31:0]$ for this 256-bit write access.

CDU write masking

30

35

The CPU performs four 64-bit word writes to 4 contiguous 256-bit DRAM addresses with the first address specified by $cdu_diu_wadr[21:3]$. The write address $cdu_diu_wadr[21:5]$ is 256-bit aligned with bits $cdu_diu_wadr[4:3]$ allowing the 64-bit word to be selected. If these 4 DRAM words lie in the same DRAM row then an efficient access will be obtained.

The command multiplexor logic must issue 4 successive accesses to 256-bit DRAM addresses $cdu_diu_wadr[21:5],+1,+2,+3$.

dau_dcu_wmask[31:0] indicates which 8 bytes (64-bits) of the 256-bit word are to be written.

dau_dcu_wmask[31:0] is calculated using cdu_diu_wadr[4:3] i.e. bits 8*cdu_diu_wadr[4:3] to 8*(cdu_diu_wadr[4:3]+1)-1 of dau_dcu_wmask[31:0] are asserted.

Arbitrating non-CPU writes in advance

15

35

In the case of a non-CPU write commands, the write data must be transferred from the SoPEC requester before the write can occur. Arbitration should occur early to allow for any delay for the write data to be transferred to the DRAM.

Figure 113 indicates that write data transfer over 64-bit busses will take a further 4 cycles after the address is transferred. The arbitration must therefore occur 4 cycles in advance of arbitration for read accesses, Figure 109 and Figure 110, or for CPU writes Figure 112. Arbitration of CDU write accesses, Figure 114, should take place 1 cycle in advance of arbitration for read and CPU write accesses. To simplify implementation CDU write accesses are arbitrated 4 cycles in advance, similar to other non-CPU writes.

The Command Multiplexor generates another version of re_arbitrate called re_arbitrate_wadv based on the signal dcu_dau_wadv from the DCU. In the 3 cycle DRAM access dcu_dau_adv and therefore re_arbitrate are asserted in the MSN2 state of the DCU state-machine. dcu_dau_wadv and therefore re_arbitrate_wadv will therefore be asserted in the following RST state, see Figure 117. This matches the timing required for non-CPU writes shown in Figure 113 and Figure 114.

re_arbitrate_wadv causes the Arbitration Logic to perform an arbitration for non-CPU in advance.

If the winner of this arbitration is a non-CPU write then *arb_gnt* is asserted and the arbitration winner is output on *arb_sel[4:0]* and *dir_sel[1:0]*. Otherwise *arb_gnt* is not asserted.

25 Since non-CPU write commands are arbitrated early, the non-CPU command is not issued to the DCU immediately but instead written into an advance command register.

If a DCU command is in progress then the arbitration in advance of a non-CPU write command will overwrite the steering multiplexor input to the command issuing logic. The arbitration in advance happens in the DCU *MSN1* state. The new command is available at the steering multiplexor in the *MSN2* state. The command in progress will have been latched in the DRAM by *MSN* falling at the start of the *MSN1* state.

Issuing non-CPU write commands

The *arb_sel[4:0]* and *dir_sel[1:0]* values generated by the Arbitration Logic reflect the *out of order* arbitration sequence.

This out of order arbitration sequence is exported to the Read Write Data Multiplexor sub-block. This is so that write data in available in time for the actual write operation to DRAM. Otherwise a latency would be introduced every time a write command is selected.

However, the Command Multiplexor must execute the command stream in-order.

In-order command execution is achieved by waiting until *re_arbitrate* has advanced to the non-CPU write timeslot from which *re_arbitrate_wadv* has previously issued a non-CPU write written to the advance command register.

If *re_arbitrate_wadv* arbitrates a non-CPU write in advance then within the Arbitration Logic the timeslot is marked to indicate whether a write was issued.

- When *re_arbitrate* advances to a write timeslot in the Arbitration Logic then one of two actions can occur depending on whether the slot was marked by *re_arbitrate_wadv* to indicate whether a write was issued or not.
 - Non-CPU write arbitrated by re_arbitrate_wadv

15

20

25

35

If the timeslot has been marked as having issued a write then the arbitration logic responds to $re_arbitrate$ by issuing $arb_sel[4:0]$, $dir_sel[1:0]$ and asserting arb_gnt as for a normal arbitration but selecting a non-CPU write access. Normally, $re_arbitrate$ does not issue non-CPU write accesses. Non-CPU writes are arbitrated by $re_arbitrate_wadv$. $dir_sel[1:0] == 00$ indicates a non-CPU write issued by $re_arbitrate$.

The command multiplexor does not write the command into the advance command register as it has already been placed there earlier by $re_arbitrate_wadv$. Instead, the already present write command in the advance command register is issued when $write_data_valid[1] = 1$. Note, that the value of $arb_sel[4:0]$ issued by $re_arbitrate$ could specify a different write than that in the advance command register since time has advanced. It is always the command in the advance command register that is issued. The steering multiplexor in this case must not issue an acknowledge back to SoPEC requester indicated by the value of $arb_sel[4:0]$.

Non-CPU write not arbitrated by re_arbitrate_wadv

If the timeslot has been marked as not having issued a write, the *re_arbitrate* will use the un-used read timeslot selection to replace the un-used write timeslot with a read timeslot according to Section 20.10.6.2 Unused read timeslots allocation.

The mechanism for write timeslot arbitration selects non-CPU writes in advance. But the selected non-CPU write is stored in the Command Multiplexor and issued when the write data is available.

This means that even if this timeslot is overwritten by the CPU reprogramming the timeslot before the write command is actually issued to the DRAM, the originally arbitrated non-CPU write will always be correctly issued.

5 Accepting write commands

When a write command is issued then write_data_accept[1:0] is asserted. This tells the Write Multiplexor that the current write data has been accepted by the DRAM and the write multiplexor can receive write data from the next arbitration winner if it is a write. write_data_accept[1:0] differentiates between CPU and non-CPU writes. A write command is known to have been issued when re_arbitrate_wadv to decide on the next command is detected.

In the case of CDU writes the DCU will generate a signal dcu_dau_cduwaccept which tells the Command Multiplexor to issue a write_data_accept[1]. This will result in the Write Multiplexor supplying the next CDU write data to the DRAM.

15

10

Debug logic output to CPU Configuration and Arbitration Logic sub-block write_sel[4:0] reflects the value of arb_sel[4:0] at the command issuing logic. The signal write_complete is asserted when every any bit of write_data_accept[1:0] is asserted.

write_sel[4:0] and write_complete are CPU readable from the DIUPerformance and WritePerformance status registers. When write_complete is asserted write_sel[4:0] will indicate which write access the DAU has issued.

20.14.12.1 CPU Interface and Configuration Registers Description

The CPU Interface and Configuration Registers sub-block provides for the CPU to access DAU specific registers by reading or writing to the DAU address space.

The CPU subsystem bus interface is described in more detail in Section 11.4.3. The DAU block will only allow supervisor mode accesses to data space (i.e. $cpu_acode[1:0] = b11$). All other accesses will result in diu_cpu_berr being asserted.

The configuration registers described in Section 20.14.9

20.14.12.2 Arbitration Logic Description

Arbitration is triggered by the signal *re_arbitrate* from the Command Multiplexor sub-block with the signal *arb_gnt* indicating that arbitration has occurred and the arbitration winner is indicated by *arb_sel[4:0]*. The encoding of *arb_sel[4:0]* is shown in Table . The signal *dir_sel[1:0]* indicates if the arbitration winner is a read, write or refresh. Arbitration should complete within one clock cycle so *arb_gnt* is normally asserted the clock cycle after *re_arbitrate* and stays high for 1 clock cycle. *arb_sel[4:0]* and *dir_sel[1:0]* remain persistent until arbitration occurs again. The arbitration timing is shown in Figure 119.

10 20.14.12.2.1 Rotation Synchronisation

A configuration bit, *RotationSync*, is used to initialise advancement through the timeslot rotation, in order that the CPU will know, on a cycle basis, which timeslot is being arbitrated. This is essential for debug purposes, so that exact arbitration sequences can be reproduced.

In general, if *RotationSync* is set, slots continue to be arbitrated in the regular order specified by the timeslot rotation. When the bit is cleared, the current rotation continues until the slot pointers for pre- and main arbitration reach zero. The arbitration logic then grants DRAM access exclusively to the CPU and refreshes.

When the CPU again writes to *RotationSync* to cause a 0-to-1 transition of the bit, the *rdy* acknowledgment back to the CPU for this write will be exactly coincident with the RST cycle of the initial refresh which heralds the enabling of a new rotation. This refresh, along with the second access which can be either a CPU pre-access or a refresh, (depending on the CPU's request inputs), form a 2-access "preamble" before the first non-CPU requester in the new rotation can be serviced. This preamble is necessary to give the write pre-arbitration the necessary head start on the main arbitration, so that write data can be loaded in time. See Figure 105 below. The same preamble procedure is followed when emerging from reset.

The alignment of *rdy* with the commencement of the rotation ensures that the CPU is always able to calculate at any point how far a rotation has progressed. *RotationSync* has a reset value of 1 to ensure that the default power-up rotation can take place.

Note that any CPU writes to the DIU's other configuration registers should only be made when *RotationSync* is cleared. This ensures that accesses by non-CPU requesters to DRAM are not affected by *partial* configuration updates which have yet to be completed.

20.14.12.2.2 Motivation for Rotation Synchronisation

15

30

40

- The motivation for this feature is that communications with SoPEC from external sources are synchronised to the internal clock of our position within a DIU full timeslot rotation. This means that if an external source told SOPEC to start a print 3 separate times, it would likely be at three different points within a full DIU rotation. This difference means that the DIU arbitration for each of the runs would be different, which would manifest itself externally as anomalous or inconsistent print performance. The lack of reproducibility is the problem here.
 - However, if in response to the external source saying to start the print, we caused the internal to pass through a known state at a fixed time offset to other internal actions, this would result in reproducible prints. So, the plan is that the software would do a rotation synchronise action, then writes "Go" into various PEP units to cause the prints. This means the DIU state will be the identical with respect to the PEP units state between separate runs.
 - 20.14.12.2.3 Wind-down Protocol when Rotation Synchronisation is Initiated When a zero is written to "RotationSync", this initiates a "wind-down protocol" in the DIU, in which any rotation already begun must be fully completed. The protocol implements the following sequence:-
- The pre-arbitration logic must reach the end of whatever rotation *it* is on and stop pre-arbitrating.
 - Only when this has happened, does the main arbitration consider doing likewise with its
 current rotation. Note that the main arbitration lags the pre-arbitration by at least 2 DRAM
 accesses, subject to variation by CPU pre-accesses and/or scheduled refreshes, so that the
 two arbitration processes are sometimes on different rotations.

 Once the main arbitration has reached the end of its rotation, rotation synchronisation is considered to be fully activated. Arbitration then proceeds as outlined in the next section.

20.14.12.2.4 Arbitration during Rotation Synchronisation

Note that when *RotationSync* is '0' and, assuming the terminating rotation has completely drained out, then DRAM arbitration is granted according to the following fixed priority order :-

Scheduled Refresh -> CPU(W) -> CPU(R) -> Default Refresh.

CPU pre-access counters play no part in arbitration during this period. It is only subsequently, when emerging from rotation sync, that they are reloaded with the values of CPUPreAccessTimeslots and CPUTotalTimeslots and normal service resumes.

10 20.14.12.2.5 Timeslot-based arbitration

5

Timeslot-based arbitration works by having a pointer point to the current timeslot. This is shown in Figure 95 repeated here as Figure 121. When re-arbitration is signaled the arbitration winner is the current timeslot and the pointer advances to the next timeslot. Each timeslot denotes a single access. The duration of the timeslot depends on the access.

15 If the SoPEC Unit assigned to the current timeslot is not requesting then the unused timeslot arbitration mechanism outlined in Section 20.10.6 is used to select the arbitration winner. Note that this unused slot re-allocation is guaranteed to produce a result, because of the inclusion of refresh in the round-robin scheme.

20 Pseudo-code to represent arbitration is given below:

```
if re_arbitrate == 1 then
                                arb gnt = 1
                           if current timeslot requesting then
25
                                   choose (arb_sel,
                                                       dir sel)
                                                                   at.
                                                                          current
                  timeslot
                           else // un-used timeslot scheme
                                     choose
                                               winner
                                                        according
                                                                    to
                                                                         un-used
                  timeslot allocation of Section 20.10.6
30
                                arb gnt = 0
```

20.14.12.3 Arbitrating non-CPU writes in advance

In the case of a non-CPU write commands, the write data must be transferred from the SoPEC requester before the write can occur. Arbitration should occur early to allow for any delay for the write data to be transferred to the DRAM.

Figure 113 indicates that write data transfer over 64-bit busses will take a further 4 cycles after the address is transferred. The arbitration must therefore occur 4 cycles in advance of arbitration for read accesses, Figure 109 and Figure 110, or for CPU writes Figure 112. Arbitration of CDU write accesses, Figure 114, should take place 1 cycle in advance of arbitration for read and CPU write accesses. To simplify implementation CDU write accesses are arbitrated 4 cycles in advance, similar to other non-CPU writes.

The Command Multiplexor generates a second arbitration signal *re_arbitrate_wadv* which initiates the arbitration in advance of non-CPU write accesses.

The timeslot scheme is then modified to have 2 separate pointers:

5

20

35

- re_arbitrate can arbitrate read, refresh and CPU read and write accesses according to the position of the current timeslot pointer.
- re_arbitrate_wadv can arbitrate only non-CPU write accesses according to the position of the write lookahead pointer.

Pseudo-code to represent arbitration is given below:

If the SoPEC Unit assigned to the current timeslot is not requesting then the unused read timeslot arbitration mechanism outlined in Section 20.10.6.2 is used to select the arbitration winner.

re_arbitrate is generated in the MSN2 state of the DCU state-machine, whereas re_arbitrate_wadv is generated in the RST state. See Figure 103.

The write lookahead pointer points two timeslots in advance of the current timeslot pointer.

Therefore re_arbitrate_wadv causes the Arbitration Logic to perform an arbitration for non-CPU
two timeslots in advance. As noted in Table , each timeslot lasts at least 3 cycles. Therefor
re_arbitrate_wadv arbitrates at least 4 cycles in advance.

At initialisation, the write lookahead pointer points to the first timeslot. The current timeslot pointer is invalid until the write lookahead pointer advances to the third timeslot when the current timeslot pointer will point to the first timeslot. Then both pointers advance in tandem.

Some accesses can be preceded by a CPU access as in Table These CPU accesses are not allocated timeslots. If this is the case the timeslot will last 3 (CPU access) + 3 (non-CPU access) = 6 cycles. In that case, a second write lookahead pointer, the CPU pre-access write lookahead pointer, is selected which points only one timeslot in advance. $re_arbitrate_wadv$ will still arbitrate 4 cycles in advance.

20.14.12.3.1 Issuing non-CPU write commands

5

40

Although the Arbitration Logic will arbitrate non-CPU writes in advance, the Command Multiplexor must issue all accesses in the timeslot order. This is achieved as follows:

If re_arbitrate_wadv arbitrates a non-CPU write in advance then within the Arbitration Logic the timeslot is marked to indicate whether a write was issued.

```
15
                 //re_arbitrate_wadv
                 if (re arbitrate wadv == 1) AND (write lookahead timeslot
                 pointer == non-CPU write)
                                             then
                   if write lookahead timeslot requesting then
                        choose(arb sel, dir sel) at write lookahead timeslot
20
                     arb qnt = 1
                     MARK timeslot = 1
                   elsif un-used write timeslot scheme has a requestor
                     choose winner according to un-used write timeslot
                 allocation of Section 20.10.6.1
25
                     arb gnt = 1
                     MARK timeslot = 1
                     //no pre-arbitration winner
                     arb_gnt = 0
30
                     MARK timeslot = 0
```

When re_arbitrate advances to a write timeslot in the Arbitration Logic then one of two actions can occur depending on whether the slot was marked by re_arbitrate_wadv to indicate whether a write was issued or not.

Non-CPU write arbitrated by re_arbitrate_wadv

If the timeslot has been marked as having issued a write then the arbitration logic responds to re_arbitrate by issuing arb_sel[4:0], dir_sel[1:0] and asserting arb_gnt as for a normal arbitration but selecting a non-CPU write access. Normally, re_arbitrate does not issue non-CPU write accesses. Non-CPU writes are arbitrated by re_arbitrate_wadv. dir_sel[1:0] == 00 indicates a non-CPU write issued by re_arbitrate.

Non-CPU write not arbitrated by re_arbitrate_wadv

If the timeslot has been marked as not having issued a write, the re_arbitrate will use the un-used read timeslot selection to replace the un-used write timeslot with a read timeslot according to Section 20.10.6.2 Unused read timeslots allocation.

```
5
                 //re arbitrate except for non-CPU writes
                 if (re arbitrate == 1) AND (current timeslot pointer!= non-
                 CPU write) then
                  .arb gnt = 1
                   if current timeslot requesting then
10
                       choose(arb_sel, dir_sel) at current timeslot
                   else // un-used read timeslot scheme
                     choose winner according to un-used read timeslot
                 allocation of Section 20.10.6.2
                     arb qnt = 1
15
                 //non-CPU write MARKED as issued
                 elsif (re arbitrate == 1) AND (current timeslot pointer ==
                 non-CPU write) AND
                        (MARK timeslot == 1) then
20
                       //indicate to Command Multiplexor that non-CPU write
                 has been arbitrated in
                       //advance
                       arb gnt = 1
                       dir sel[1:0] == 00
25
                 //non-CPU write not MARKED as issued
                 elsif (re arbitrate == 1) AND (current timeslot pointer ==
                 non-CPU write) AND
                        (MARK timeslot == 0) then
30
                     choose winner according to un-used read timeslot
                 allocation of Section 20.10.6.2
                     arb_gnt = 1
```

20.14.12.4 Flow control

45

If read commands are to win arbitration, the Read Multiplexor must be ready to accept the read data from the DRAM. This is indicated by the *read_cmd_rdy[1:0]* signal. *read_cmd_rdy[1:0]* supplies flow control from the Read Multiplexor.

```
read_cmd_rdy[0] == 1 //Read multiplexor ready for CPU

read
read_cmd_rdy[1] == 1 //Read multiplexor ready for non-CPU
read
```

The Read Multiplexor will normally always accept CPU reads, see Section 20.14.13.1, so read_cmd_rdy[0]==1 should always apply.

Similarly, if write commands are to win arbitration, the Write Multiplexor must be ready to accept the write data from the winning SoPEC requestor. This is indicated by the write_cmd_rdy[1:0] signal. write_cmd_rdy[1:0] supplies flow control from the Write Multiplexor.

The Write Multiplexor will normally always accept CPU writes, see Section 20.14.13.2, so write_cmd_rdy[0]==1 should always apply.

Non-CPU read flow control

15

If re_arbitrate selects an access then the signal dau_dcu_msn2stall is asserted until the Read Write Multiplexor is ready.

arb_gnt is not asserted until the Read Write Multiplexor is ready.

This mechanism will stall the DCU access to the DRAM until the Read Write Multiplexor is ready to accept the next data from the DRAM in the case of a read.

20.14.12.5 Arbitration Hierarchy

CPU and refresh are not included in the timeslot allocations defined in the DAU configuration registers of Table .

- 30 The hierarchy of arbitration under normal operation is
 - a. CPU access
 - b. Refresh access
 - c. Timeslot access.

This is shown in Figure 124. The first DRAM access issued after reset *must* be a refresh.

As shown in Figure 118, the DIU request signals <unit>_diu_rreq, <unit>_diu_wreq are registered at the input of the arbitration block to ease timing. The exceptions are the refresh_req signal, which is generated locally in the sub-block and cpu_diu_rreq. The CPU read request signal is not registered so as to keep CPU DIU read access latency to a minimum. Since CPU writes are posted, cpu_diu_wreq is registered so that the DAU can process the write at a later juncture. The arbitration logic is coded to perform arbitration of non-CPU requests first and then to gate the result with the CPU requests. In this way the CPU can make the requests available late in the arbitration cycle.

Note that when *RotationSync* is set to '0', a modified hierarchy of arbitration is used. This is outlined in section 20.14.12.2.3 on page 280.

20.14.12.6 Timeslot access

20

25

40

The basic timeslot arbitration is based on the *MainTimeslot* configuration registers. Arbitration works by the timeslot pointed to by either the current or write lookahead pointer winning arbitration. The pointers then advance to the next timeslot. This was shown in Figure 90.

Each main timeslot pointer gets advanced each time it is accessed regardless of whether the slot is used.

20.14.12.7 Unused timeslot allocation

- 10 If an assigned slot is not used (because its corresponding SoPEC Unit is not requesting) then it is reassigned according to the scheme described in Section 20.10.6.
 - Only used non-CPU accesses are reallocated. CDU write accesses cannot be included in the unused timeslot allocation for write as CDU accesses take 6 cycles. The write accesses which the CDU write could otherwise replace require only 3 or 4 cycles.
- 15 Unused write accesses are re-allocated according to the fixed priority scheme of Table . Unused read timeslots are re-allocated according to the two-level round-robin scheme described in Section 20.10.6.2.
 - A pointer points to the most recently re-allocated unit in each of the round-robin levels. If the unit immediately succedling the pointer is requesting, then this unit wins the arbitration and the pointer is advanced to reflect the new winner. If this is not the case, then the subsequent units (wrapping back eventually to the pointed unit) in the level 1 round-robin are examined. When a requesting unit is found this unit wins the arbitration and the pointer is adjusted. If no unit is requesting then the pointer does not advance and the second level of round-robin is examined in a similar fashion. In the following pseudo-code the bit indices are for the *ReadRoundRobinLevel* configuration register described in Table .

Round-robin arbitration is effectively a priority assignment with the units assigned a priority according to the round-robin order of Table but starting at the unit currently pointed to.

//levelptr is pointer of selected round robin level

priority is array 0 to 11 // index 0 is SCBR(0) etc. from Table

The arbitration winner is the one with the highest priority provided it is requesting and its ReadRoundRobinLevel bit points to the chosen level. The levelptr is advanced to the arbitration winner.

The priority comparison can be done in the hierarchical manner shown in Figure 125.

20.14.12.8 How Non-CPU Address Restrictions Affect Arbitration

Recall from Table "DAU configuration registers," on page 288, " DAU configuration registers," on page 268 that there are minimum valid DRAM addresses for non-CPU accesses, defined by minNonCPUReadAdr, minDWUWriteAdr and minNonCPUWriteAdr. Similarly, a non-CPU requester may not try to access a location above the high memory mark.

To ensure compliance with these address restrictions, the following DIU response occurs for any incorrectly addressed non-CPU *writes*:-

- Issue a write acknowledgment at pre-arbitration time, to prevent the write requester from hanging.
- Disregard the incoming write data and write valids and void the pre-arbitration.
- Subsequently re-allocate the write slot at main arbitration time via the round robin.
- 25 For any incorrectly addressed non-CPU reads, the response is :-
 - Arbitrate the slot in favour of the scheduled, misbehaving requester.
 - Issue the read acknowledgement and rvalids to keep the requester from hanging.
 - Intercept the read data coming from the DCU and send back all zeros instead.

If an invalidly addressed non-CPU access is attempted, then a sticky bit,

30 *sticky_invalid_non_cpu_adr*, is set in the *ArbitrationHistory* configuration register. See Table n page 293 on page 275 for details.

20.14.12.9 Refresh Controller Description

20

40

The refresh controller implements the functionality described in detail in Section 20.10.5. Refresh is not included in the timeslot allocations.

35 CPU and refresh have priority over other accesses. If the refresh controller is requesting i.e. refresh_req is asserted, then the refresh request will win any arbitration initiated by re_arbitrate. When the refresh has won the arbitration refresh_req is de-asserted.

The refresh counter is reset to *RefreshPeriod[8:0]* i.e. the number of cycles between each refresh. Every time this counter decrements to 0, a refresh is issued by asserting *refresh_req*. The counter immediately reloads with the value in *RefreshPeriod[8:0]* and continues its countdown. It does not wait for an acknowledgment, since the priority of a refresh request supersedes that of any

pending non-CPU access and it will be serviced immediately. In this way, a refresh request is guaranteed to occur every (RefreshPeriod[8:0] + 1) cycles. A given refresh request may incur some incidental delay in being serviced, due to alignment with DRAM accesses and the possibility of a higher-priority CPU pre-access.

Refresh is also included in the unused read and write timeslot allocation, having second option on awards to a round-robin position shared with the CPU. A refresh issued as a result of an unused timeslot allocation also causes the refresh counter to reload with the value in *RefreshPeriod[8:0]*. The first access issued by the DAU after reset must be a refresh. This assures that refreshes for all DRAM words fall within the required 3.2ms window.

10

```
//issue a refresh request if counter reaches 0 or at
                 reset or for re-allocated slot
                      if RefreshPeriod != 0 AND
                                                      (refresh cnt
                                                                            OR
                          diu soft reset n == 0 OR
15
                                           prst_n
                                                             ==0
                                                                            OR
                 unused timeslot allocation == 1) then
                        refresh req = 1
                      //de-assert refresh request when refresh acked
                      else if refresh ack == 1 then
20
                        refresh_req = 0
                      //refresh counter
                   if refresh_cnt == 0 OR diu_soft_reset_n == 0 OR prst_n ==0
                                             OR unused timeslot allocation ==
25
                                             1 then
                        refresh_cnt = RefreshPeriod
                      else
                        refresh_cnt = refresh_cnt - 1
```

30

Refresh can preceded by a CPU access in the same way as any other access. This is controlled by the *CPUPreAccessTimeslots* and *CPUTotalTimeslots* configuration registers. Refresh will therefore not affect CPU performance. A sequence of accesses including refresh might therefore be CPU, refresh, CPU, actual timeslot.

35 20.14.12.10 CPU Timeslot Controller Description

CPU accesses have priority over all other accesses. CPU access is not included in the timeslot allocations. CPU access is controlled by the *CPUPreAccessTimeslots* and *CPUTotalTimeslots* configuration registers.

To avoid the CPU having to wait for its next timeslot it is desirable to have a mechanism for ensuring that the CPU always gets the next available timeslot without incurring any latency on the non-CPU timeslots.

This is be done by defining each timeslot as consisting of a CPU access preceding a non-CPU access. Two counters of 4-bits each are defined allowing the CPU to get a maximum of

(CPUPreAccessTimeslots + 1) pre-accesses out of a total of (CPUTotalTimeslots + 1) main slots. A timeslot counter starts at CPUTotalTimeslots and decrements every timeslot, while another counter starts at CPUPreAccessTimeslots and decrements every timeslot in which the CPU uses its access. If the pre-access entitlement is used up before (CPUTotalTimeslots +1) slots, no

further CPU accesses are allowed. When the *CPUTotalTimeslots* counter reaches zero both counters are reset to their respective initial values.

When *CPUPreAccessTimeslots* is set to zero then only one pre-access will occur during every (CPUTotalTimeslots + 1) slots.

20.14.12.10.1 Conserving CPU Pre-Accesses

- In section 20.10.6.2.1 on page 249, it is described how the CPU can be allowed participate in the unused read round-robin scheme. When enabled by the configuration bit EnableCPURoundRobin, the CPU shares a joint position in the round robin with refresh. In this case, the CPU has priority, ahead of refresh, in availing of any unused slot awarded to this position.
- Such CPU round-robin accesses do *not* count towards depleting the CPU's quota of preaccesses, specified by *CPUPreAccessTimeslots*. Note that in order to conserve these preaccesses, the arbitration logic, when faced with the choice of servicing a CPU request either by a pre-access or by an immediately following unused read slot which the CPU is poised to win, will opt for the latter.
- 20 20.14.13 Read and Write Data Multiplexor sub-block

Table 138. Read and Write Multiplexor Sub-block IO Definition

Port name	Pins	1/0	Description			
Clocks and Resets						
Pclk	1	ln	System Clock			
prst_n	1	In	System reset, synchronous active low

read_sel .	5	Out	Signal indicating the SoPEC Unit for which the current read transaction is occurring. Encoding is described in Table .	
read_complete	1	Out	Signal indicating that read transaction to SoPEC Unit indicated by read_sel is complete.	

20.14.13.1 Read Multiplexor logic description

The Read Multiplexor has 2 read channels

5

- a separate read bus for the CPU, dram_cpu_data[255:0].
- and a shared read bus for the rest of SoPEC, diu_data[63:0].

The validity of data on the data busses is indicated by signals diu_<unit>_rvalid.

Timing waveforms for non-CPU and CPU DIU read accesses are shown in Figure 90 and Figure 91, respectively.

- The Read Multiplexor timing is shown in Figure 127. Figure 127 shows both CPU and non-CPU reads. Both CPU and non-CPU channels are independent i.e. data can be output on the CPU read bus while non-CPU data is being transmitted in 4 cycles over the shared 64-bit read bus. CPU read data, dram_cpu_data[255:0], is available in the same cycle as output from the DCU. CPU read data needs to be registered immediately on entering the CPU by a flip-flop enabled by the diu_cpu_rvalid signal.
- To ease timing, non-CPU read data from the DCU is first registered in the Read Multiplexor by capturing it in the shared read data buffer of Figure 126 enabled by the dcu_dau_rvalid signal. The data is then partitioned in 64-bit words on diu_data[63:0].
 - 20.14.13.1.1 Non-CPU Read Data Coherency

Note that for data coherency reasons, a non-CPU read will always result in read data being returned to the requester which includes the after-effects of any pending (i.e. pre-arbitrated, but not yet executed) non-CPU write to the same address, which is currently cached in the non-CPU

write buffer. This is shown graphically in Figure n page319 on page Error! B okmark n t defined..

Should the pending write be partially *masked*, then the read data returned must take account of that mask. Pending, masked writes by the CDU and SCB, as well as all unmasked non-CPU writes are fully supported.

Since *CPU* writes are dealt with on a dedicated write channel, no attempt is made to implement coherency between posted, unexecuted CPU writes and non-CPU reads to the same address.

20.14.13.1.2 Read multiplexor command gueue

5

15

25

30

When the Arbitration Logic sub-block issues a read command the associated value of arb_sel[4:0], which indicates which SoPEC Unit has won arbitration, is written into a buffer, the read command gueue.

```
write_en = arb_gnt AND dir_sel[1:0] == "01"
if write_en == 1 then
    WRITE arb sel into read command queue
```

The encoding of *arb_sel[4:0]* is given in Table . *dir_sel[1:0]=="01"* indicates that the operation is a read. The read command queue is shown in Figure 128.

The command queue could contain values of arb_sel[4:0] for 3 reads at a time.

- In the scenario of Figure 127 the command queue can contain 2 values of *arb_sel[4:0]* i.e. for the simultaneous CDU and CPU accesses.
 - In the scenario of Figure 130, the command queue can contain 3 values of arb_sel[4:0] i.e. at the time of the second dcu_dau_rvalid pulse the command queue will contain an arb_sel[4:0] for the arbitration performed in that cycle, and the two previous arb_sel[4:0] values associated with the data for the first two dcu_dau_rvalid pulses, the data associated with the first dcu_dau_rvalid pulse not having been fully transferred over the shared read data bus.

The read command queue is specified as 4 deep so it is never expected to fill.

The top of the command queue is a signal *read_type[4:0]* which indicates the destination of the current read data. The encoding of *read_type[4:0]* is given in Table .

```
20.14.13.1.3 CPU reads
```

Read data for the CPU goes straight out on dram_cpu_data[255:0] and dcu_dau_rvalid is output on diu_cpu_rvalid.

cpu_read_complete(0) is asserted when a CPU read at the top of the read command queue occurs. cpu_read_complete(0) causes the read command queue to be popped.

```
cpu_read_complete(0) = (read_type[4:0] == CPU read) AND
(dcu_dau_rvalid == 1)
```

If the current read command queue location points to a non-CPU access and the second read command queue location points to a CPU access then the next dcu_dau_rvalid pulse received is

associated with a CPU access. This is the scenario illustrated in Figure 127. The dcu_dau_rvalid pulse from the DCU must be output to the CPU as diu_cpu_rvalid. This is achieved by using cpu_read_complete(1) to multiplex dcu_dau_rvalid to diu_cpu_rvalid. cpu_read_complete(1) is also used to pop the second from top read command queue location from the read command queue.

20.14.13.1.4 Multiplexing dcu_dau_rvalid

5

10

15

35

read_type[4:0] and cpu_read_complete(1) multiplexes the data valid signal, dcu_dau_rvalid, from the DCU, between the CPU and the shared read bus logic. diu_cpu_rvalid is the read valid signal going to the CPU. noncpu_rvalid is the read valid signal used by the Read Multiplexor control logic to generate read valid signals for non-CPU reads.

```
if read_type[4:0] == CPU-read then
                      //select CPU
                         diu cpu rvalid:= 1
20
                         noncpu_rvalid:= 0
                      if
                                (read type[4:0] ==
                                                        non-CPU-read)
                                                                             AND
                  SECOND(read_type[4:0] == CPU-read)
                         AND dcu_dau_rvalid == 1 then
                      //select CPU
25
                         diu_cpu_rvalid:= 1
                         noncpu rvalid:= 0
                      else
                         //select shared read bus logic
                         diu cpu rvalid:= 0
30
                         noncpu_rvalid:= 1
```

20.14.13.1.5 Non-CPU reads

Read data for the shared read bus is registered in the shared read data buffer using noncpu_rvalid. The shared read buffer has 5 locations of 64 bits with separate read pointer, read_ptr[2:0], and write pointer, write_ptr[2:0].

```
shared_read_data_buffer[write_ptr+3]
dcu_dau_data[255:192]
```

The data written into the shared read buffer must be output to the correct SoPEC DIU read requestor according to the value of read_type[4:0] at the top of the command queue. The data is output 64 bits at a time on diu_data[63:0] according to a multiplexor controlled by read_ptr[2:0].

```
diu_data[63:0] = shared_read_data_buffer[read_ptr]
```

Figure 126 shows how read_type[4:0] also selects which shared read bus requesters

diu_<unit>_rvalid signal is connected to shared_rvalid. Since the data from the DCU is registered in the Read Multiplexor then shared_rvalid is a delayed version of noncpu_rvalid.

When the read valid, diu_<unit>_rvalid, for the command associated with read_type[4:0] has been asserted for 4 cycles then a signal shared_read_complete is asserted. This indicates that the read has completed. shared_read_complete causes the value of read_type[4:0] in the read command queue to be popped.

A state machine for shared read bus access is shown in Figure 129. This show the generation of shared_rvalid, shared_read_complete and the shared read data buffer read pointer, read_ptr[2:0], being incremented.

Some points to note from Figure 129 are:

5

25

- shared_rvalid is asserted the cycle after dcu_dau_rvalid associated with a shared read bus access. This matches the cycle delay in capturing dau_dcu_data[255:0] in the shared read data buffer. shared_rvalid remains asserted in the case of back to back shared read bus accesses.
 - shared_read_complete is asserted in the last shared_rvalid cycle of a non-CPU access. shared_read_complete causes the shared read data queue to be popped.

20.14.13.1.6 Read command queue read pointer logic

The read command queue read pointer logic works as follows.

```
if shared_read_complete == 1 OR cpu_read_complete(0) == 1
then

POP top of read command queue
if cpu_read_complete(1) == 1 then

POP second read command queue location
```

20.14.13.1.7 Debug signals

35 shared_read_complete and cpu_read_complete together define read_complete which indicates to the debug logic that a read has completed. The source of the read is indicated on read_sel[4:0].

```
read_complete = shared_read_complete OR
cpu_read_complete(0)

OR cpu_read_complete(1)

if cpu_read_complete(1) == 1 then
    read_sel:= SECOND(read_type)
```

else
 read_sel:= read_type

20.14.13.1.8 Flow control

15

25

35

There are separate indications that the Read Multiplexor is able to accept CPU and shared read bus commands from the Arbitration Logic. These are indicated by read_cmd_rdy[1:0].

The Arbitration Logic can always issue CPU reads except if the read command queue fills. The read command queue should be large enough that this should never occur.

10 //Read Multiplexor ready for Arbitration Logic to issue CPU reads

read_cmd_rdy[0] == read command queue not full

For the shared read data, the Read Multiplexor deasserts the shared read bus read_cmd_rdy[1] indication until a space is available in the read command queue. The read command queue should be large enough that this should never occur.

read_cmd_rdy[1] is also deasserted to provide flow control back to the Arbitration Logic to keep the shared read data bus just full.

//Read Multiplexor not ready for Arbitration Logic to
issue non-CPU reads

read_cmd_rdy[1] = (read command queue not full) AND

(flow_control = 0)

The flow control condition is that DCU read data from the second of two back-to-back shared read bus accesses becomes available. This causes *read_cmd_rdy[1]* to de-assert for 1 cycle, resulting in a repeated MSN2 DCU state. The timing is shown in Figure 130.

```
flow_control = (read_type[4:0] == non-CPU read)

AND SECOND(read_type[4:0] == non-

CPU read)

AND (current DCU state == MSN2)

AND (previous DCU state == MSN1).
```

Figure 130 shows a series of back to back transfers over the shared read data bus. The exact timing of the implementation must not introduce any additional latency on shared read bus read transfers i.e. arbitration must be re-enabled just in time to keep back to back shared read bus data full.

The following sequence of events is illustrated in Figure 130:

- Data from the first DRAM access is written into the shared read data buffer.
- Data from the second access is available 3 cycles later, but its transfer into the shared read buffer is delayed by a cycle, due to the MSN2 stall condition. (During this delay, read data

for access 2 is maintained at the output of the DRAM.) A similar 1-cycle delay is introduced for every subsequent read access until the back-to-back sequence comes to an end.

 Note that arbitration always occurs during the last MSN2 state of any access. So, for the second and later of any back-to-back non-CPU reads, arbitration is delayed by one cycle, i.e. it occurs every fourth cycle instead of the standard every third.

This mechanism provides flow control back to the Arbitration Logic sub-block. Using this mechanism means that the access rate will be limited to which ever takes longer - DRAM access or transfer of read data over the shared read data bus. CPU reads are always be accepted by the Read Multiplexor.

10 20.14.13.2 Write Multiplexor logic description

The Write Multiplexor supplies write data to the DCU.

There are two separate write channels, one for CPU data on cpu_diu_wdata[127:0], one for non-CPU data on non_cpu_wdata[255:0]. A signal write_data_valid[1:0] indicates to the Command Multiplexor that the data is valid. The Command Multiplexor then asserts a signal

write_data_accept[1:0] indicating that the data has been captured by the DRAM and the appropriate channel in the Write Multiplexor can accept the next write data.

Timing waveforms for write accesses are shown in Figure 92 to Figure 94, respectively. There are 3 types of write accesses:

CPU accesses

5

20 CPU write data on cpu_diu_wdata[127:0] is output on cpu_wdata[127:0]. Since CPU writes are posted, a local buffer is used to store the write data, address and mask until the CPU wins arbitration. This buffer is one position deep. write_data_valid[0], which is synonymous with !diu_cpu_write_rdy, remains asserted until the Command Multiplexor indicates it has been written to the DRAM by asserting write_data_accept[0]. The CPU write buffer can then accept new posted writes.

For non-CPU writes, the Write Multiplexor multiplexes the write data from the DIU write requester to the write data buffer and the *<unit>_diu_wvalid* signal to the write multiplexor control logic.

CDU accesses

30

35

64-bits of write data each for a masked write to a separate 256-bit word are transferred to the Write Multiplexor over 4 cycles.

When a CDU write is selected the first 64-bits of write data on <code>cdu_diu_wdata[63:0]</code> are multiplexed to non_cpu_wdata[63:0]. <code>write_data_valid[1]</code> is asserted to indicate a non-CPU access when <code>cdu_diu_wvalid</code> is asserted. The data is also written into the first location in the write data buffer. This is so that the data can continue to be output on non_cpu_wdata[63:0] and <code>write_data_valid[1]</code> remains asserted until the Command

- non_cpu_wdata[63:0] and write_data_valid[1] remains asserted until the Command Multiplexor indicates it has been written to the DRAM by asserting write_data_accept[1]. Data continues to be accepted from the CDU and is written into the other locations in the write data buffer. Successive write_data_accept[1] pulses cause the successive 64-bit data words to be output on wdata[63:0] together with write_data_valid[1]. The last
- 40 write_data_accept[1] means the write buffer is empty and new write data can be accepted.

Other write accesses.

5

10

20

30

35

256-bits of write data are transferred to the Write Multiplexor over 4 successive cycles. When a write is selected the first 64-bits of write data on <unit>_diu_wdata[63:0] are written into the write data buffer. The next 64-bits of data are written to the buffer in successive cycles. Once the last 64-bit word is available on <unit>_diu_wdata[63:0] the entire word is output on non_cpu_wdata[255:0], write_data_valid [1] is asserted to indicate a non-CPU access, and the last 64-bit word is written into the last location in the write data buffer. Data continues to be output on non_cpu_wdata[255:0] and write_data_valid[1] remains asserted until the Command Multiplexor indicates it has been written to the DRAM by asserting write_data_accept[1]. New write data can then be written into the write buffer.

CPU write multiplexor control logic

When the Command Multiplexor has issued the CPU write it asserts write_data_accept[0]. write_data_accept[0] causes the write multiplexor to assert write_cmd_rdy[0].

The signal *write_cmd_rdy[0]* tells the Arbitration Logic sub-block that it can issue another CPU write command i.e. the CPU write data buffer is empty.

Non-CPU write multiplexor control logic

The signal write_cmd_rdy[1] tells the Arbitration Logic sub-block that the Write Multiplexor is ready to accept another non-CPU write command. When write_cmd_rdy[1] is asserted the Arbitration Logic can issue a write command to the Write Multiplexor. It does this by writing the value of arb_sel[4:0] which indicates which SoPEC Unit has won arbitration into a write command register, write_cmd[3:0].

The encoding of $arb_sel[4:0]$ is given in Table . $dir_sel[1]==1$ indicates that the operation is a write. $arb_sel[4:0]$ is only written to the write command register if the write is a non-CPU write.

A rule was introduced in Section 20.7.2.3 Interleaving read and write accesses to the effect that non-CPU write accesses would not be allocated adjacent timeslots. This means that a single write command register is required.

The write command register, write_cmd[3:0], indicates the source of the write data. write_cmd[3:0] multiplexes the write data <unit>_diu_wdata, and the data valid signal, <unit>_diu_wvalid, from the selected write requestor to the write data buffer. Note, that CPU write data is not included in the multiplex as the CPU has its own write channel. The <unit>_diu_wvalid are counted to generate the signal word_sel[1:0] which decides which 64-bit word of the write data buffer to store the data from <unit>_diu_wdata.

```
//when the Command Multiplexor accepts the write data if write data accept[1] = 1 then
```

wvalid is the <unit>_diu_wvalid signal multiplexed by write_cmd[3:0]. word_sel[1:0] is reset when the Command Multiplexor accepts the write data. This is to ensure that word_sel[1:0] is always starts at 00 for the first wvalid pulse of a 4 cycle write data transfer.

The write command register is able to accept the next write when the Command Multiplexor accepts the write data by asserting <code>write_data_accept[1]</code>. Only the last <code>write_data_accept[1]</code> pulse associated with a CDU access (there are 4) will cause the write command register to be ready to accept the next write data.

Flow control back to the Command Multiplexor

write_cmd_rdy[0] is asserted when the CPU data buffer is empty.

write_cmd_rdy[1] is asserted when both the write command register and the write data buffer is

PEP SUBSYSTEM

empty.

15

20

40

21 PEP Controller Unit (PCU)

21.1 OVERVIEW

The PCU has three functions:

- The first is to act as a bus bridge between the CPU-bus and the PCU-bus for reading and writing PEP configuration registers.
 - The second is to support page banding by allowing the PEP blocks to be reprogrammed between bands by retrieving commands from DRAM instead of being programmed directly by the CPU.
- The third is to send register debug information to the RDU, within the CPU subsystem, when the PCU is in Debug Mode.
 - 21.2 INTERFACES BETWEEN PCU AND OTHER UNITS
 - 21.3 Bus Bridge

The PCU is a bus-bridge between the CPU-bus and the PCU-bus. The PCU is a slave on the CPU-bus but is the only master on the PCU-bus. See Figure page39 on page **Error! Bookmark not defined..**

21.3.1 CPU accessing PEP

All the blocks in the PEP can be addressed by the CPU via the PCU. The MMÜ in the CPU-subsystem will decode a PCU select signal, *cpu_pcu_sel*, for all the PCU mapped addresses (see section 11.4.3 on page 69). Using *cpu_adr* bits 15-12 the PCU will decode individual block selects for each of the blocks within the PEP. The PEP blocks then decode the remaining address bits

needed to address their PCU-bus mapped registers. Note: the CPU is only permitted to perform supervisor-mode data-type accesses of the PEP, i.e. $cpu_acode = 11$. If the PCU is selected by the CPU and any other code is present on the cpu_acode bus the access is ignored by the PCU and the pcu_cpu_berr signal is strobed,

- 5 CPU commands have priority over DRAM commands. When the PCU is executing each set of four commands retrieved from DRAM the CPU can access PCU-bus registers. In the case that DRAM commands are being executed and the CPU resets the *CmdSource* to zero, the contents of the DRAM *CmdFifo* is invalidated and no further commands from the fifo are executed. The *CmdPending* and *NextBandCmdEnable* work registers are also cleared.
- When a DRAM command writes to the *CmdAdr* register it means the next DRAM access will occur at the address written to *CmdAdr*. Therefore if the JUMP instruction is the first command in a group of four, the other three commands get executed and then the PCU will issue a read request to DRAM at the address specified by the JUMP instruction. If the JUMP instruction is the second command then the following two commands will be executed before the PCU requests from the new DRAM address specified by the JUMP instruction etc. Therefore the PCU will always execute the remaining commands in each four command group before carrying out the JUMP instruction.

21.4 PAGE BANDING

20

25

30

35

40

The PCU can be programmed to associate microcode in DRAM with each *finishedband* signal. When a *finishedband* signal is asserted the PCU will read commands from DRAM and execute these commands. These commands are each 64-bits (see Section 21.8.5) and consist of 32-bit address bits and 32 data bits and allow PCU mapped registers to be programmed directly by the PCU.

If more than one *finishedband* signal is received at the same time, or others are received while microcode is already executing, the PCU will hold the commands as pending, and will execute them at the first opportunity.

Each microcode program associated with <code>cdu_finishedband</code>, <code>lbd_finishedband</code> and <code>te_finishedband</code> would simply restart the appropriate unit with new addresses - a total of about 4 or 5 microcode instructions. As well, or alternatively, <code>pcu_finishedband</code> can be used to set up all of the units and therefore involves many more instructions. This minimizes the time that a unit is idle in between bands. The <code>pcu_finishedband</code> control signal is issued once the specified combination of CDU, LBD and TE (programmed in <code>BandSelectMask</code>) have finished their processing for a band.

21.5 INTERRUPTS, ADDRESS LEGALITY AND SECURITY

Interrupts are generated when the various page expansion units have finished a particular band of data from DRAM. The *cdu_finishedband*, *lbd_finishedband* and *te_finishedband* signals are combined in the PCU into a single interrupt *pcu_finishedband* which is exported by the PCU to the interrupt controller.

The PCU mapped registers should only be accessible from Supervisor Data Mode. The area of DRAM where PCU commands are stored should be a Supervisor Mode only DRAM area, although this is not enforced by the PCU.

When the PCU is executing commands from DRAM, any block-address decoded from a command which is not part of the PEP block-address map will cause the PCU to ignore the command and strobe the *pcu_icu_address_invalid* interrupt signal. The CPU can then interrogate the PCU to find the source of the illegal command. The MMU will ensure that the CPU cannot address an invalid PEP subsystem block.

When the PCU is executing commands from DRAM, any address decoded from a command which is not part of the PEP address map will cause the PCU to:

- Cease execution of current command and flush all remaining commands already retrieved from DRAM.
- Clear CmdPending work-register.

5

15

20

- Clear NextBandCmdEnable registers.
- Set CmdSource to zero.

In addition to cancelling all current and pending DRAM accesses the PCU strobes the pcu_icu_address_invalid interrupt signal. The CPU can then interrogate the PCU to find the source of the illegal command.

21.6 DEBUG MODE

When the need to monitor the (possibly changing) value in any PEP configuration register the PCU may be placed in Debug Mode. This is done via the CPU setting certain Debug Address register within the PCU. Once in Debug Mode the PCU continually reads the target PEP configuration register and sends the read value to the RDU. Debug Mode has the lowest priority of all PCU functions: if the CPU wishes to perform an access or there are DRAM commands to be executed they will interrupt the Debug access, and the PCU will resume Debug access once a CPU or DRAM command has completed.

21.7 IMPLEMENTATION

25 21.7.1 Definitions of I/O

Table 139, PCU Port List

Port Name	Pins	1/0	Description.				
Clocks and Resets							
Pclk	1	ln	SoPEC functional clock				
prst_n	1	In	Active-low, synchronous reset in pclk domain				
End of Band Functionality							
cdu_finishedband	1	ln	Finished band signal from CDU				
lbd_finishedband	1	ln	Finished band signal from LBD				
te_finishedband	1	In	Finished band signal from TE				
pcu_finishedband	1	Out	Asserted once the specified combination of CDU, LBD, and TE have finished their processing for a band.				
PCU address error		.1					

pcu_icu_address_invalid	1	Out	Strobed if PCU decodes a non PEP address from		
			commands retrieved from DRAM or CPU.		
CPU Subsystem Interface	Siar	l als			
cpu_adr[15:2]	14	In	CPU address bus. 14 bits are required to decode the		
	' '		address space for the PEP.		
cpu_dataout[31:0]	32	ln	Shared write data bus from the CPU		
	32				
pcu_cpu_data[31:0]	ļ	Out	Read data bus to the CPU		
cpu_rwn	1	In	Common read/not-write signal from the CPU		
cpu_acode[1:0]	2	ln	CPU Access Code signals. These decode as follows:		
			00 - User program access		
			01 - User data access		
			10 - Supervisor program access		
			11 - Supervisor data access		
cpu_pcu_sel	1	ln	Block select from the CPU. When cpu_pcu_sel is		
			high both <i>cpu_adr</i> and <i>cpu_dataout</i> are valid		
pcu_cpu_rdy	1	Out	Ready signal to the CPU. When pcu_cpu_rdy is high		
			it indicates the last cycle of the access. For a write		
			cycle this means cpu_dataout has been registered by		
			the block and for a read cycle this means the data on		
			pcu_cpu_data is valid.		
pcu_cpu_berr	1	Out	Bus error signal to the CPU indicating an invalid		
			access.		
pcu_cpu_debug_valid	1	Out	Debug Data valid on pcu_cpu_data bus. Active high.		
PCU Interface to PEP blo	cks				
pcu_adr[11:2]	10	Out	PCU address bus. The 10 least significant bits of		
	ŧ		cpu_adr [15:2] allow 1024 32-bit word addressable		
			locations per PEP block. Only the number of bits		
			required to decode the address space are exported		
			to each block.		
pcu_dataout[31:0]	32	Out	Shared write data bus from the PCU		
<pre></pre>	32	In	Read data bus from each PEP subblock to the PCU		
pcu_rwn .	1	Out	Common read/not-write signal from the PCU		
pcu_ <unit>_sel</unit>	1	Out	Block select for each PEP block from the PCU.		
			Decoded from the 4 most significant bits of		
			cpu_adr[15:2]. When pcu_ <unit>_sel is high both</unit>		
			pcu_adr and pcu_dataout are valid		
<unit>_pcu_rdy</unit>	1	ln	Ready from each PEP block signal to the PCU.		
		[When <unit>_pcu_rdy is high it indicates the last</unit>		
			cycle of the access. For a write cycle this means		
		<u></u>	cycle of the decess. For a white eyele this means		

			pcu_dataout has been registered by the block and for			
			a read cycle this means the data on			
			<unit>_pcu_datain is valid.</unit>			
DIU Read Interface sig	nals					
pcu_diu_rreq	1	Out	PCU requests DRAM read. A read request must be			
			accompanied by a valid read address.			
pcu_diu_radr[21:5]	17	Out	Read address to DIU			
			17 bits wide (256-bit aligned word).			
diu_pcu_rack	1	ln	Acknowledge from DIU that read request has been			
			accepted and new read address can be placed on			
			pcu_diu_radr			
diu_data[63:0]	64	In	Data from DIU to PCU.			
			First 64-bits is bits 63:0 of 256 bit word			
			Second 64-bits is bits 127:64 of 256 bit word			
			Third 64-bits is bits 191:128 of 256 bit word			
			Fourth 64-bits is bits 255:192 of 256 bit word			
diu_pcu_rvalid	1	ln	Signal from DIU telling PCU that valid read data is on			
			the <i>diu_data</i> bus			

21.7.2 Configuration Registers

Table 140. PCU Configuration Registers

Address	register	#bits	reset	description		
PCU_base+						
Control registers						
0x00	Reset	1	0x1	A write to this register causes a reset of the		
				PCU.		
				This register can be read to indicate the reset		
				state:		
				0 - reset in progress		
				1 - reset not in progress		
0x04	CmdAdr[21:	17	0×00 000	The address of the next set of commands to		
	5]	:		retrieve from DRAM.		
	(256-bit			When this register is written to, either by the		
	aligned			CPU or DRAM command, 1 is also written to		
	DRAM			CmdSource to cause the execution of the		
	address)			commands at the specified address.		
0x08	BandSelect	3	0x0	Selects which input finishedBand flags are to

	t[15:2]		:	of the register to report on the pcu_cpu_data
				bus when it is not otherwise being used, and
				the PEP bus is not being used
				Bits [15:12] select the unit (see Table)
				Bits [11:2] select the register within the unit
Work registers (re	ead only)		<u> </u>	
0x28	InvalidAddre	19	ю	DRAM Address of current 64-bit command
	ss[21:3]		ľ	attempting to execute.
	(64-bit			Read only register.
	aligned			reducting register.
	DRAM)		1	
0.20			000	For each hit with an in O.A. 2
0x2C	CmdPendin	5	0x00	For each bit n, where n is 0 to 3
•	y			0 -no commands pending for
				NextBandCmdAdr[n]
				1 -commands pending for
				NextBandCmdAdr[n]

				For bit 4 0 -no commands pending for NextCmdAdr[n]
				1 -commands pending for NextCmdAdr[n] Read only register.
0x34	FinishedSo 3	3		The appropriate bit is set whenever the corre-
	Far			sponding input finishedBand flag is set and
				the corresponding bit in the BandSelectMask
				bit is also set.
				lf all <i>FinishedSoFar</i> bits are set wherever
				BandSelect bits are also set, all
		:	:	FinishedSoFar bits are cleared and the output
				pcu_finishedband signal is given.
				Read only register.
0x38	NextBandC 4	ı	0x0	This register can be written to indirectly (i.e.
	mdEnable			the bits are set or cleared via writes to
				NextBandCmdAdr[n])
				For each bit:
				0 - do nothing at the next finishedBand[n]
				signal.
				1 - Execute instructions at
				NextBandCmdAdr[n] as soon as possible
				after receipt of the next finishedBand[n]
				signal.
				Bit0 - lbd_finishedband
				Bit1 - cdu_finishedband
				Bit2 - te_finishedband
				Bit3 - pcu_finishedband
				Read only register.

21.8 DETAILED DESCRIPTION

5

21.8.1 PEP Blocks Register Map

All PEP accesses are 32-bit register accesses.

From Table 140 it can be seen that four bits only are necessary to address each of the subblocks within the PEP part of SoPEC. Up to 14 bits may be used to address any configurable 32bit register within PEP. This gives scope for 1024 configurable registers per sub-block. This address will come either from the CPU or from a command stored in DRAM. The bus is assembled as follows:

- adr[15:12] = sub-block address
- adr[n:2] = 32-bit register address within sub-block, only the number of bits required to decode the registers within each sub-block are used.

Table 141. PEP blocks Register Map

Block	Block Select Decode			
	= cpu_adr[15:12]			
PCU	0x0			
CDU	0x1			
CFU	0x2			
LBD	0x3			
SFU	0x4			
TE	0x5			
TFU	0x6			
HCU	0×7			
DNC	0x8			
DWU	0x9			
LLU	0xA			
PHI	0xB			
Reserved	0xC to 0xF			

21.8.2 Internal PCU PEP protocol

The PCU performs PEP configuration register accesses via a select signal, $pcu_<block>_sel$. The read/ write sense of the access is communicated via the pcu_rwn signal (1 = read, 0 = write).

Write data is clocked out, and read data clocked in upon receipt of the appropriate selectread/write-address combination.

Figure 133 shows a write operation followed by a read operation. The read operation is shown with wait states while the PEP block returns the read data.

For access to the PEP blocks a simple bus protocol is used. The PCU first determines which

10 particular PEP block is being addressed so that the appropriate block select signal can be
generated. During a write access PCU write data is driven out with the address and block select
signals in the first cycle of an access. The addressed PEP block responds by asserting its ready
signal indicating that it has registered the write data and the access can complete. The write data
bus is common to all PEP blocks.

A read access is initiated by driving the address and select signals during the first cycle of an access. The addressed PEP block responds by placing the read data on its bus and asserting its ready signal to indicate to the PCU that the read data is valid. Each block has a separate point-to-point data bus for read accesses to avoid the need for a tri-stateable bus.

Consecutive accesses to a PEP block must be separated by at least a single cycle, during which the select signal must be de-asserted.

21.8.3 PCU DRAM access requirements

20

The PCU can execute register programming commands stored in DRAM. These commands can be executed at the start of a print run to initialize all the registers of PEP. The PCU can also execute instructions at the start of a page, and between bands. In the inter-band time, it is critical

to have the PCU operate as fast as possible. Therefore in the inter-page and inter-band time the PCU needs to get low latency access to DRAM.

A typical band change requires on the order of 4 commands to restart each of the CDU, LBD, and TE, followed by a single command to terminate the DRAM command stream. This is on the order of 5 commands per restart component.

The PCU does single 256 bit reads from DRAM. Each PCU command is 64 bits so each 256 bit DRAM read can contain 4 PCU commands. The requested command is read from DRAM together with the next 3 contiguous 64-bits which are cached to avoid unnecessary DRAM reads. Writing zero to *CmdSource* causes the PCU to flush commands and terminate program access

from DRAM for that command stream. The PCU requires a 256-bit buffer to the 4 PCU commands read by each 256-bit DRAM access. When the buffer is empty the PCU can request DRAM access again. Adding a 256-bit double buffer would allow the next set of 4 commands to be fetched from DRAM while the current commands are being executed.

1024 commands of 64 bits requires 8 kB of DRAM storage.

15 Programs stored in DRAM are referred to as PCU Program Code.

21.8.4 End of band unit

5

The state machine is responsible for watching the various input xx_finishedband signals, setting the FinishedSoFar flags, and outputting the pcu_finishedband flags as specified by the BandSelect register.

Each cycle, the end of band unit performs the following tasks:

```
pcu finishedband = (FinishedSoFar[0] == BandSelectMask[0])
                 AND
                                        (FinishedSoFar[1]
                                                                              ==
25
                 BandSelectMask[1]) AND
                                        (FinishedSoFar[2]
                                                                              ==
                 BandSelectMask[2]) AND
                                        (BandSelectMask[0]
                                                                              OR
                 BandSelectMask[1] OR BandSelectMask[2])
30
                    if (pcu finishedband == 1) then
                      FinishedSoFar[0] = 0
                      FinishedSoFar[1] = 0
                      FinishedSoFar[2] = 0
                    else
35
                      FinishedSoFar[0]
                                                      (FinishedSoFar[0]
                                                                              OR
                 lbd finishedband) AND BandSelectMask[0]
                      FinishedSoFar[1]
                                                      (FinishedSoFar[1]
                                                                              OR
                  cdu finishedband) AND BandSelectMask[1]
                      FinishedSoFar[2]
                                                      (FinishedSoFar[2]
                                                                              OR
40
                  te_finishedband) AND BandSelectMask[2]
```

Note that it is the responsibility of the microcode at the start of printing a page to ensure that all 3 *FinishedSoFar* bits are cleared. It is not necessary to clear them between bands since this happens automatically.

If a bit of *BandSelectMask* is cleared, then the corresponding bit of *FinishedSoFar* has no impact on the generation of *pcu_finishedband*.

21.8.5 Executing commands from DRAM

5

10

20

25

30

35

Registers in PEP can be programmed by means of simple 64-bit commands fetched from DRAM. The format of the commands is given in Table 142. Register locations can have a data value of up to 32 bits. Commands are PEP register write commands only.

Table 142. Register write commands in PEP

command	bits 63-32	2 bits 31-16	bits 15-2	bits 1-0
Register write	data	zero	32-bit word	zero
			address	

Due attention must be paid to the endianness of the processor. The LEON processor is a bigendian processor (bit 7 is the most significant bit).

21.8.6 General Operation

15 Upon a Reset condition, *CmdSource* is cleared (to 0), which means that all commands are initially sourced only from the CPU bus interface. Registers and can then be written to or read from one location at a time via the CPU bus interface.

If *CmdSource* is 1, commands are sourced from the DRAM at *CmdAdr* and from the CPU bus. Writing an address to *CmdAdr* automatically sets *CmdSource* to 1, and causes a command stream to be retrieved from DRAM. The PCU will execute commands from the CPU or from the DRAM command stream, giving higher priority to the CPU always.

If *CmdSource* is 0 the DRAM requestor examines the *CmdPending* bits to determine if a new DRAM command stream is pending. If any of *CmdPending* bits are set, then the appropriate *NextBandCmdAdr* or *NextCmdAdr* is copied to *CmdAdr* (causing *CmdSource* to get set to 1) and a new command DRAM stream is retrieved from DRAM and executed by the PCU. If there are multiple pending commands the DRAM requestor will service the lowest number pending bit first. Note that a new DRAM command stream only gets retrieved when the current command stream is empty.

If there are no DRAM commands pending, and no CPU commands the PCU defaults to an idle state. When idle the PCU address bus defaults to the *DebugSelect* register value (bits 11 to 2 in particular) and the default unit PCU data bus is reflected to the CPU data bus. The default unit is determined by the *DebugSelect* register bits 15 to 12.

In conjunction with this, upon receipt of a *finishedBand[n]* signal, *NextBandCmdEnable[n]* is copied to *CmdPending[n]* and *NextBandCmdEnable[n]* is cleared. Note, each of the LBD, CDU, and TE (where present) may be re-programmed individually between bands by appropriately setting *NextBandCmdAdr[2-0]* respectively. However, execution of inter-band commands may be postponed until all blocks specified in the *BandSelectMask* register have pulsed their *finishedband*

signal. This may be accomplished by only setting NextBandCmdAdr[3] (indirectly causing NextBandCmdEnable[3] to be set) in which case it is the pcu_finishedband signal which causes NextBandCmdEnable[3] to be copied to CmdPending[3].

To conveniently update multiple registers, for example at the start of printing a page, a series of

Write Register commands can be stored in DRAM. When the start address of the first Write
Register command is written to the *CmdAdr* register (via the CPU), the *CmdSource* register is
automatically set to 1 to actually start the execution at *CmdAdr*. Alternatively the CPU can write to
NextCmdAdr causing the CmdPending[4] bit to get set, which will then get serviced by the DRAM
requestor in the pending bit arbitration order.

The final instruction in the command block stored in DRAM must be a register write of 0 to CmdSource so that no more commands are read from DRAM. Subsequent commands will come from pending programs or can be sent via the CPU bus interface.

21.8.6.1 Debug Mode

15

20

Debug mode is implemented by reusing the normal CPU and DRAM access decode logic. When in the *Arbitrate* state (see state machine A below), the PEP address bus is defaulted to the value in the *DebugSelect* register. The top bits of the *DebugSelect* register are used to decode a select to a PEP unit and the remaining bits are reflected on the PEP address bus. The selected units read data bus is reflected on the *pcu_cpu_data* bus to the RDU in the CPU. The *pcu_cpu_debug_valid* signal indicates to the RDU that the data on the *pcu_cpu_data* bus is valid debug data.

Normal CPU and DRAM command access will require the PEP bus, and as such will cause the debug data to be invalid during the access, this is indicated to the RDU by setting pcu_cpu_debug_valid to zero.

The decode logic is:

```
25
                  // Default Debug decode
                  if state == Arbitrate then
                           (cpu pcu sel
                                                         AND
                                                                 cpu acode
                  SUPERVISOR DATA MODE) then
                      pcu_cpu_debug_valid
                                                                   // bus error
                                                       0
30
                  condition
                                                 = 0
                      pcu_cpu_data
                    else
                                                 = decode (DebugSelect [15:12])
                      if (<unit> == PCU ) then
35
                         pcu cpu data
                                                = Internal PCU register
                      else
                                                = <unit> pcu datain[31:0]
                         pcu cpu data
                      pcu_adr[11:2]
                                                 = DebugSelect[11:2]
                      pcu cpu debug valid
                                                 = 1 AFTER 4 clock cycles
40
                  else
                                                 = 0
                    pcu_cpu_debug_valid
             State Machines
     21.8.7
```

DRAM command fetching and general command execution is accomplished using two state machines. State machine A evaluates whether a CPU or DRAM command is being executed, and proceeds to execute the command(s). Since the CPU has priority over the DRAM it is permitted to interrupt the execution of a stream of DRAM commands.

Machine B decides which address should be used for DRAM access, fetches commands from DRAM and fills a command fifo which A executes. The reason for separating the two functions is to facilitate the execution of CPU or Debug commands while state machine B is performing DRAM reads and filling the command fifo. In the case where state machine A is ready to execute commands (in its *Arbitrate* state) and it sees both a full DRAM command fifo and an active cpu_pcu_sel then the DRAM commands are executed last.

21.8.7.1 State Machine A: Arbitration and execution of commands

The state-machine enters the *Reset* state when there is an active strobe on either the reset pin, *prst_n*, or the PCU's soft-reset register. All registers in the PCU are zeroed, unless otherwise specified, on the next rising clock edge. The PCU self-deasserts the soft reset in the *pclk* cycle after it has been asserted.

The state changes from Reset to Arbitrate when $prst_n == 1$ and $PCU_softreset == 1$.

The state-machine waits in the *Arbitrate* state until it detects a request for CPU access to the PEP units (*cpu_pcu_sel* == 1 and *cpu_acode* == 11) or a request to execute DRAM commands *CmdSource* == 1, and DRAM commands are available, *CmdFifoFull*==1. Note if (*cpu_pcu_sel* == 1 and *cpu_acode*!= 11) the CPU is attempting an illegal access. The PCU ignores this command and strobes the *cpu_pcu_berr* for one cycle.

While in the *Arbitrate* state the machine assigns the *DebugSelect* register to the PCU unit decode logic and the remaining bits to the PEP address bus. When in this state the debug data returned from the selected PEP unit is reflected on the CPU bus (pcu_cpu_data bus) and the

25 pcu_cpu_debug_valid=1.

15

20

30

40

If a CPU access request is detected (cpu_pcu_sel == 1 and cpu_acode == 11) then the machine proceeds to the CpuAccess state. In the CpuAccess state the cpu address is decoded and used to determine the PEP unit to select. The remaining address bits are passed through to the PEP address bus. The machine remains in the CpuAccess state until a valid ready from the selected PEP unit is received. When received the machine returns to the arbitrate state, and the ready signal to the CPU is pulsed.

```
// decode the logic
pcu_<unit>_sel = decode(cpu_adr[15:12])
pcu adr[11:2] = cpu adr[11:2]
```

The CPU is prevented from generating an invalid PEP unit address (prevented in the MMU) and so CPU accesses cannot generate an invalid address error.

If the state machine detects a request to execute DRAM commands (*CmdSource* == 1), it will wait in the *Arbitrate* state until commands have been loaded into the command FIFO from DRAM (all controlled by state machine B). When the DRAM commands are available (*cmd_fifo_full* == 1) the state machine will proceed to the *DRAMAccess* state.

When in the *DRAMAccess* state the commands are executed from the *cmd_fifo*. A command in the *cmd_fifo* consists of 64-bits (or which the FIFO holds 4). The decoding of the 64-bits to commands is given in Table . For each command the decode is

```
// DRAM command decode

pcu_<unit>_sel = decode( cmd_fifo[cmd_count][15:12] )

pcu_adr[11:2] = cmd_fifo[cmd_count][11:2]

pcu_dataout = cmd_fifo[cmd_count][63:32]
```

When the selected PEP unit returns a ready signal (<unit>_pcu_rdy==1) indicating the command has completed, the state machine will return to the *Arbitrate* state. If more commands exists (cmd_count !=0) the transition will decrement the command count.

- When in the *DRAMAccess* state, if when decoding the DRAM command address bus (*cmd_fifo[cmd_count][15:12]*), the address selects a reserved address, the state machine proceeds to the *AdrError* state, and then back to the *Arbitrate* state. An address error interrupt will be generated and the DRAM command FIFOs will be cleared.
- 15 A CPU access can pre-empt any pending DRAM commands. After each command is completed the state machine returns to the *Arbitrate* state. If a CPU access is required and DRAM command stream is executing the CPU access always takes priority. If a CPU or DRAM command sets the *CmdSource* to 0, all subsequent DRAM commands in the command FIFO are cleared. If the CPU sets the *CmdSource* to 0 the *CmdPending* and *NextBandCmdEnable* work registers are also cleared.
 - 21.8.7.2 State Machine B: Fetching DRAM commands

10

25

30

35

40

A system reset (*prst_n==*0) or a software reset (*pcu_softreset_n==*0) will cause the state machine to reset to the *Reset* state. The state machine remains in the *Reset* until both reset conditions are removed. When removed the machine proceeds to the *Wait* state.

- The state machine waits in the *Wait* state until it determines that commands are needed from DRAM. Two possible conditions exist that require DRAM access. Either the PCU is processing commands which must be fetched from DRAM (*cmd_source==1*), and the command FIFO is empty (*cmd_fifo_full==0*), or the *cmd_source==0* and the command FIFO is empty and there are some commands pending (*cmd_pending!=0*). In either of these conditions the machine proceeds to the *Ack* state and issues a read request to DRAM (*pcu_diu_rreq==1*), it calculates the address to read from dependent on the transition condition. In the command pending transition condition, the highest priority *NextBandCmdAdr* (or *NextCmdAdr*) that is pending is used for the read address (*pcu_diu_radr*) and is also copied to the *CmdAdr* register. If multiple pending bits are set the lowest pending bits are serviced first. In the normal PCU processing transition the *pcu_diu_radr* is the *CmdAdr* register.
 - When an acknowledge is received from the DRAM the state machine goes to the *FillFifo* state. In the *FillFifo* state the machine waits for the DRAM to respond to the read request and transfer data words. On receipt of the first word of data *diu_pcu_rvalid==1*, the machine stores the 64-bit data word in the command FIFO (*cmd_fifo[3]*) and transitions to the *Data1*, *Data2*, *Data3* states each time waiting for a *diu_pcu_rvalid==1* and storing the transferred data word to *cmd_fifo[2]*, *cmd_fifo[1]* and *cmd_fifo[0]* respectively.

When the transfer is complete the machine returns to the *Wait* state, setting the *cmd_count* to 3, the *cmd_fifo_full* is set to 1 and the *CmdAdr* is incremented.

If the CPU sets the *CmdSource* register low while the PCU is in the middle of a DRAM access, the statemachine returns to the *Wait* state and the DRAM access is aborted.

5 21.8.7.3 PCU_ICU_Address_Invalid Interrupt

When the PCU is executing commands from DRAM, addresses decoded from commands which are not PCU mapped addresses (4-bits only) will result in the current command being ignored and the pcu_icu_address_invalid interrupt signal is strobed. When an invalid command occurs all remaining commands already retrieved from DRAM are flushed from the CmdFifo, and the

10 CmdPending, NextBandCmdEnable and CmdSource registers are cleared to zero.

The CPU can then interrogate the PCU to find the source of the illegal DRAM command via the *InvalidAddress* register.

The CPU is prevented by the MMU from generating an invalid address command.

- 22 Contone Decoder Unit (CDU)
- **15** 22.1 OVERVIEW

30

The Contone Decoder Unit (CDU) is responsible for performing the optional decompression of the contone data layer.

The input to the CDU is up to 4 planes of compressed contone data in JPEG interleaved format. This will typically be 3 planes, representing a CMY contone image, or 4 planes representing a CMYK contone image. The CDU must support a page of A4 length (11.7 inches) and Letter width (8.5 inches) at a resolution of 267 ppi in 4 colors and a print speed of 1 side per 2 seconds. The CDU and the other page expansion units support the notion of page banding. A compressed page is divided into one or more bands, with a number of bands stored in memory. As a band of the page is consumed for printing a new band can be downloaded. The new band may be for the current page or the next page. Band-finish interrupts have been provided to notify the CPU of free buffer space.

The compressed contone data is read from the on-chip DRAM. The output of the CDU is the decompressed contone data, separated into planes. The decompressed contone image is written to a circular buffer in DRAM with an expected minimum size of 12 lines and a configurable maximum. The decompressed contone image is subsequently read a line at a time by the CFU, optionally color converted, scaled up to 1600 ppi and then passed on to the HCU for the next stage in the printing pipeline. The CDU also outputs a *cdu_finishedband* control flag indicating that the CDU has finished reading a band of compressed contone data in DRAM and that area of DRAM is now free. This flag is used by the PCU and is available as an interrupt to the CPU.

35 22.2 STORAGE REQUIREMENTS FOR DECOMPRESSED CONTONE DATA IN DRAM A single SoPEC must support a page of A4 length (11.7 inches) and Letter width (8.5 inches) at a resolution of 267 ppi in 4 colors and a print speed of 1 side per 2 seconds. The printheads specified in the Bi-lithic Printhead Specification [2] have 13824 nozzles per color to provide full bleed printing for A4 and Letter. At 267 ppi, there are 2304 contone pixels⁹ per line represented by 288 JPEG blocks per color. However each of these blocks actually stores data for 8 lines, since a single JPEG block is 8 x 8 pixels. The CDU produces contone data for 8 lines in parallel, while the HCU processes data linearly across a line on a line by line basis. The contone data is decoded only once and then buffered in DRAM. This means we require two sets of 8 buffer-lines - one set of 8 buffer lines is being consumed by the CFU while the other set of 8 buffer lines is being generated by the CDU.

5

10

15

20

25

The buffer requirement can be reduced by using a 1.5 buffering scheme, where the CDU fills 8 lines while the CFU consumes 4 lines. The buffer space required is a minimum of 12 line stores per color, for a total space of 108 KBytes¹⁰. A circular buffer scheme is employed whereby the CDU may only begin to write a line of JPEG blocks (equals 8 lines of contone data) when there are 8-lines free in the buffer. Once the full 8 lines have been written by the CDU, the CFU may now begin to read them on a line by line basis.

This reduction in buffering comes with the cost of an increased peak bandwidth requirement for the CDU write access to DRAM. The CDU must be able to write the decompressed contone at twice the rate at which the CFU reads the data. To allow for trade-offs to be made between peak bandwidth and amount of storage, the size of the circular buffer is configurable. For example, if the circular buffer is configured to be 16 lines it behaves like a double-buffer scheme where the peak bandwidth requirements of the CDU and CFU are equal. An increase over 16 lines allows the CDU to write ahead of the CFU and provides it with a margin to cope with very poor local compression ratios in the image.

SoPEC should also provide support for A3 printing and printing at resolutions above 267 ppi. This increases the storage requirement for the decompressed contone data (buffer) in DRAM. Table 143 gives the storage requirements for the decompressed contone data at some sample contone resolutions for different page sizes. It assumes 4 color planes of contone data and a 1.5 buffering scheme.

Table 143. Storage requirements for decompressed contone data (buffer)

Page	Contone resolution	Scale	Pixels per line	Storage required
size	(ppi)	factor ^a		(kBytes)
A4/Letter ^b	267	6	2304	108 ^d
	400	4	3456	162
	800	2	6912	324
A3°	267	6	3248	152.25
	400	4	4872	228.37
	800	2	9744	456.75

⁹Pixels may be 8, 16, 24 or 32 bits depending on the number of color planes (8-bits per color)

¹⁰12 lines x 4 colors x 2304 bytes (assumes 267 ppi, 4 color, full bleed A4/Letter)

- a. Required for CFU to convert to final output at 1600 dpi
- b. Bi-lithic printhead has 13824 nozzles per color providing full bleed printing for A4/Letter
- c. Bi-lithic printhead has 19488 nozzles per color providing full bleed printing for A3
- 5 d. 12 lines x 4 colors x 2304 bytes.

10

25

30

22.3 DECOMPRESSION PERFORMANCE REQUIREMENTS

it capable of decoding at a peak output rate of 8 bits/cycle. SoPEC processes 1 dot (bi-level in 6 colors) per system clock cycle to achieve a print speed of 1 side per 2 seconds for full bleed A4/Letter printing. The CFU replicates pixels a scale factor (SF) number of times in both the horizontal and vertical directions to convert the final output to 1600 ppi. Thus the CFU consumes a 4 color pixel (32 bits) every SF x SF cycles. The 1.5 buffering scheme described in section 22.2 on page 327 means that the CDU must write the data at twice this rate. With support for 4 colors

The JPEG decoder core can produce a single color pixel every system clock (pclk) cycle, making

The JPEG decoder is fed directly from the main memory via the DRAM interface. The amount of compression determines the input bandwidth requirements for the CDU. As the level of compression increases, the bandwidth decreases, but the quality of the final output image can also decrease. Although the average compression ratio for contone data is expected to be 10:1, the average bandwidth allocated to the CDU allows for a local minimum compression ratio of 5:1 over a single line of JPEG blocks. This equates to a peak input bandwidth requirement of 0.36 bits/cycle for 4 colors at 267 ppi, full bleed A4/Letter printing at 1 side per 2 seconds.

at 267 ppi, the decompression output bandwidth requirement is 1.78 bits/cycle¹¹.

Table 144 gives the decompression output bandwidth requirements for different resolutions of contone data to meet a print speed of 1 side per 2 seconds. Higher resolution requires higher bandwidth and larger storage for decompressed contone data in DRAM. A resolution of 400 ppi contone data in 4 colors requires 4 bits/cycle¹², which is practical using a 1.5 buffering scheme. However, a resolution of 800 ppi would require a double buffering scheme (16 lines) so the CDU only has

to match the CFU consumption rate. In this case the decompression output bandwidth requirement is 8 bits/cycle¹³, the limiting factor being the output rate of the JPEG decoder core.

Table 144. CDU performance requirements for full bleed A4/Letter printing at 1 side per 2 seconds.

Contone	s	Scale	Decompression output bandwidth

 $^{^{11}2 \}times ((4 \text{ colors } \times 8 \text{ bits}) / (6 \times 6 \text{ cycles})) = 1.78 \text{ bits/cycle}$

 $^{^{12}2 \}times ((4 \text{ colors} \times 8 \text{ bits}) / (4 \times 4 \text{ cycles})) = 4 \text{ bits/cycle}$

 $^{^{13}}$ (4 colors x 8 bits) / (2 x 2 cycles) = 8 bits/cycle

resolution	factor	requirement (bits/cycle) ^a
(ppi)		
267	6	1.78
400	4	. 4
800	2	8 ⁶

- a. Assumes 4 color pixel contone data and a 12 line buffer.
- b. Scale factor 2 requires at least a 16 line buffer.

22.4 DATA FLOW

10

15

30

Figure 136 shows the general data flow for contone data - compressed contone planes are read from DRAM by the CDU, and the decompressed contone data is written to the 12-line circular buffer in DRAM. The line buffers are subsequently read by the CFU.

The CDU allows the contone data to be passed directly on, which will be the case if the color represented by each color plane in the JPEG image is an available ink. For example, the four colors may be C, M, Y, and K, directly represented by CMYK inks. The four colors may represent gold, metallic green etc. for multi-SoPEC printing with exact colors.

However JPEG produces better compression ratios for a given visible quality when luminance and chrominance channels are separated. With CMYK, K can be considered to be luminance, but C, M, and Y each contain luminance information, and so would need to be compressed with appropriate luminance tables. We therefore provide the means by which CMY can be passed to SoPEC as YCrCb. K does not need color conversion. When being JPEG compressed, CMY is typically converted to RGB, then to YCrCb and then finally JPEG compressed. At decompression, the YCrCb data is obtained and written to the decompressed contone store by the CDU. This is read by the CFU where the YCrCb can then be optionally color converted to RGB, and finally

The external RIP provides conversion from RGB to YCrCb, specifically to match the actual hardware implementation of the inverse transform within SoPEC, as per CCIR 601-2 [24] except that Y, Cr and Cb are normalized to occupy all 256 levels of an 8-bit binary encoding.

The CFU provides the translation to either RGB or CMY. RGB is included since it is a necessary step to produce CMY, and some printers increase their color gamut by including RGB inks as well as CMYK.

22.5 IMPLEMENTATION

back to CMY.

A block diagram of the CDU is shown in Figure 137.

All output signals from the CDU (cdu_cfu_wradv8line, cdu_finishedband, cdu_icu_jpegerror, and control signals to the DIU) must always be valid after reset. If the CDU is not currently decoding, cdu_cfu_wradv8line, cdu_finishedband and cdu_icu_jpegerror will always be 0.

The read control unit is responsible for keeping the JPEG decoder's input FIFO full by reading compressed contone bytestream from external DRAM via the DIU, and produces the *cdu_finishedband* signal. The write control unit accepts the output from the JPEG decoder a half JPEG block (32 bytes) at a time, writes it into a double-buffer, and writes the double buffered

decompressed half blocks to DRAM via the DIU, interacting with the CFU in order to share DRAM buffers.

Clocks and reset Pclk System clock. In Jclk Gated version of system clock used to clock the JPEG decoder core and logic at the output of the core. Allows for stalling of the JPEG core at a pixel sample boundary. iclk enable Out Gating signal for jclk. prst n ln System reset, synchronous active low. Reset for jclk domain, synchronous active low. irst_n ln PCU interface Block select from the PCU. When pcu_cdu_sel is pcu_cdu_sel high both *pcu_adr* and *pcu_dataout* are valid. pcu_rwn ln Common read/not-write signal from the PCU. pcu_adr[7:2] PCU address bus. Only 6 bits are required to decode the address space for this block. 32 pcu_dataout[31:0] Shared write data bus from the PCU. Out Ready signal to the PCU. When cdu_pcu_rdy is high cdu_pcu_rdy it indicates the last cycle of the access. For a write cycle this means pcu_dataout has been registered by the block and for a read cycle this means the data on cdu_pcu_datain is valid.

cdu pcu datain[31:0] 32 Out Read data bus to the PCU. DIU read interface Out CDU read request, active high. A read request must cdu_diu_rreq be accompanied by a valid read address. diu_cdu_rack Acknowledge from DIU, active high. Indicates that a read request has been accepted and the new read address can be placed on the address bus, cdu_diu_radr. cdu_diu_radr[21:5] 17 Out CDU read address. 17 bits wide (256-bit aligned word). diu_cdu_rvalid Read data valid, active high. Indicates that valid read

data is now on the read data bus, diu_data.

diu_data[63:0]	64	ln	Read data from DRAM.
DIU write interface	<u> </u>	L	
cdu_diu_wreq	1	Out	CDU write request, active high. A write request must
	 -		be accompanied by a valid write address and valid
			write data.
diu_cdu_wack	1	ln	Acknowledge from DIU, active high. Indicates that a
			write request has been accepted and the new write
			address can be placed on the address bus,
			cdu_diu_wadr.
cdu_diu_wadr[21:3]	19	Out	CDU write address. 19 bits wide (64-bit aligned
	_		word).
cdu_diu_wvalid	1	Out	Write data valid, active high. Indicates that valid data
			is now on the write data bus, cdu_diu_data.
cdu_diu_data[63:0]	64	Out	Write data bus.
CFU interface			
cfu_cdu_rdadvline	1	ln	Read line pulse, active high. Indicates that the CFU
			has finished reading a line of decompressed contone
			data to the circular buffer in DRAM and that line of
			the buffer is now free.
cdu_cfu_linestore_rdy	1	Out	Indicates if the contone line store has 1 or more lines
			available to read by the CFU.
TE and LBD interface			
cdu_start_of_bandstore[21	17	Out	Points to the 256-bit word that defines the start of the
:5]			memory area allocated for page bands.
cdu_end_of_bandstore[21:	17	Out	Points to the 256-bit word that defines the last
5]			address of the memory area allocated for page
			bands.
ICU interface			
cdu_finishedband	1	Out	CDU's finishedBand flag, active high. Interrupt to the
			CPU to indicate that the CDU has finished
			processing a band of compressed contone data in
			DRAM and that area of DRAM is now free.This
			signal goes to both the interrupt controller and the
		<u> </u>	PCU.
cdu_icu_jpegerror	1	1	Active high interrupt indicating an error has occurred
		1	in the JPEG decoding process and decompression
			has stopped. A reset of the CDU must be performed
2.5.2 Configuration region		<u> </u>	to clear this interrupt.

22.5.2 Configuration registers

The configuration registers in the CDU are programmed via the PCU interface. Refer to section 21.8.2 on page 321 for the description of the protocol and timing diagrams for reading and writing registers in the CDU. Note that since addresses in SoPEC are byte aligned and the PCU only supports 32-bit register reads and writes, the lower 2 bits of the PCU address bus are not required to decode the address space for the CDU. When reading a register that is less than 32 bits wide zeros should be returned on the upper unused bit(s) of cdu_pcu_datain . Since the CDU, LBD and TE all access the page band store, they share two registers that enable sequential memory accesses to the page band stores to be circular in nature. Table 146 lists

Table 146. Registers shared between the CDU, LBD, and TE

Address	Register name	#bits	Value on	description
(CDU_base+)			reset	
Setup registers	(remain constant during	the pro	cessing of	multiple bands)
0x80	StartOfBandStore[21:5]	17	_	Points to the 256-bit word that defines the start of the memory area allocated for page bands. Circular address generation wraps to this start address.
0x84	EndOfBandStore[21:5]	17	0x1_3FFF	Points to the 256-bit word that defines the last address of the memory area allocated for page bands. If the current read address is from this address, then instead of adding 1 to the current address, the current address will be loaded from the StartOfBandStore register.

The software reset logic should include a circuit to ensure that both the *pclk* and *jclk* domains are reset regardless of the state of the *jclk_enable* when the reset is initiated.

15 The CDU contains the following additional registers:

Table 147. CDU registers

5

10

these two registers.

Address	Register name	#bits	Value on	Description
(CDU_base+)		1	reset	
Control registe	ers			
0x00	Reset	1	0x1	A write to this register causes a reset of
				the CDU. This terminates all internal
:				operations within the CS6150. All

		F	T	configuration data previously loaded
				into the core except for the tables is
		ļ	ļ	deleted.
0.04		4	00	
0x04	Go	1	0x0	Writing 1 to this register starts the CDU.
				Writing 0 to this register halts the CDU.
				When Go is deasserted the state-
				machines go to their idle states but all
				counters and configuration registers
	:			keep their values.
				When Go is asserted all counters are
				reset, but configuration registers keep
				their values (i.e. they don't get reset).
				NextBandEnable is cleared when Go is
				asserted.
				The CFU must be started before the
				CDU is started.
				Go must remain low for at least 384 jclk
				cycles after a hardware reset (prst_n =
				0) to allow the JPEG core to complete
				its memory itnitialisation sequence.
				This register can be read to determine if
				the CDU is running (1 - running, 0 -
				stopped).
Coting as sistens		<u>.</u>		stopped).
Setup registers		=	lo o -	F
0x0C	NumLinesAvail	7	0x0	The number of image lines of data that
				there is space available for in the
		,		decompressed data buffer in DRAM.
				If this drops < 8 the CDU will stall.
				In normal operation this value will start
				off atNumBuffLines and will be
				decremented by 8 whenever the CDU
				writes a line of JPEG blocks (8 lines of
				data) to DRAM and incremented by 1
	}			whenever the CFU reads a line of data
				from DRAM.
				NumLinesAvail can be overwritten by
				the CPU to prevent the CDU from
				stalling.
0x10	MaxPlane	2	0x0	Defines the number of contone planes -
		_		1.
		<u> </u>		<u> </u>

				For example, this will be 0 for K
	:			(greyscale printing), 2 for CMY, and 3 for CMYK.
0x14	MaxBlock	13	0x000	Number of JPEG MCUs (or JPEG block
				equivalents, i.e. 8x8 bytes) in a line - 1.
0x18	BuffStartAdr[21:7]	15		Points to the start of the decompressed
				contone circular buffer in DRAM,
				aligned to a half JPEG block boundary.
				A half JPEG block consists of 4 words
				of 256-bits, enough to hold 32 contone
				pixels in 4 colors, i.e. half a JPEG
				block.
0x1C	BuffEndAdr[21:7]	15	0x0000	Points to the start of the last half JPEG
				block at the end of the decompressed
				contone circular buffer in DRAM,
1				aligned to a half JPEG block boundary.
				A half JPEG block consists of 4 words
				of 256-bits, enough to hold 32 contone
				pixels in 4 colors, i.e. half a JPEG
				block.
0x20	NumBuffLines[6:2	5	0x03	Defines size of buffer in DRAM in terms
	j			of the number of decompressed
			:	contone lines. The size of the buffer
				should be a multiple of 4 lines with a
]				minimum size of 8 lines.
0x24	BypassJpg	1	0x0	Determines whether or not the JPEG
				decoder will be bypassed (and hence
				pixels are copied directly from input to
			-	output)
				0 - don't bypass, 1 - bypass
				Should not be changed between bands.
0x30	NextBandCurr-	17	0x0_0000	The 256-bit aligned word address
	SourceAdr[21:5]			containing the start of the next band of
	-			compressed contone data in DRAM.
				This value is copied to CurrSourceAdr
				when both <i>DoneBand</i> is 1 and
				NextBandEnable is 1, or when Go
				transitions from 0 to 1.
0x34	NextBandEnd-	19	0x0_0000	The 64-bit aligned word address

	SourceAdr[21:3]	<u> </u>		containing the last bytes of the next
				band of compressed contone data in
				DRAM.
				This value is copied to EndSourceAdr
				when when both <i>DoneBand</i> is 1 and
				NextBandEnable is 1, or when Go
				transitions from 0 to 1.
020	Nov4Donal\falia		00	
0x38	NextBandValid-	3	0x0	Indicates the number of valid bytes - 1
	BytesLastFetch			in the last 64-bit fetch of the next band
				of compressed contone data from
				DRAM. eg 0 implies bits 7:0 are valid, 1
				implies bits 15:0 are valid, 7 implies all
				63:0 bits are valid etc.
				This value is copied to
				ValidBytesLastFetch when both
				DoneBand is 1 and NextBandEnable is
				1, or when <i>Go</i> transitions from 0 to 1.
0x3C	NextBandEnable	1	0x0	When <i>NextBandEnable</i> is 1 and
1				DoneBand is 1
				-NextBandCurrSourceAdr is copied to
				CurrSourceAdr,
				-NextBandEndSourceAdr is copied to
				EndSourceAdr
				-NextBandValidBytesLastFetch is
			:	copied to ValidBytesLastFetch
				-DoneBand is cleared,
				-NextBandEnable is cleared.
				NextBandEnable is cleared when Go is
				asserted.
			i	Note that <i>DoneBand</i> gets cleared
				regardless of the state of <i>Go</i> .
Read-only regi	sters	<u> </u>	l	
0x40	DoneBand	11	0×0	Specifies whether or not the current
	·			band has finished loading into the local
				FIFO. It is cleared to 0 when Go
				transitions from 0 to 1.
				When the last of the compressed
į				contone data for the band has been
				loaded into the local FIFO, the
				cdu_finishedband signal is given out

			,	1
				and the <i>DoneBand</i> flag is set.
				If NextBandEnable is 1 at this time then
				CurrSourceAdr, EndSourceAdr and
				ValidBytesLastFetch are updated with
				the values for the next band and
				DoneBand is cleared. Processing of the
				next band starts immediately.
				If NextBandEnable is 0 then the
				remainder of the CDU will continue to
				run, decompressing the data already
				loaded, while the read control unit waits
				for NextBandEnable to be set before it
				restarts.
0x44	CurrSourceAdr[21	17	0x0_0000	The current 256-bit aligned word
	:5]			address within the current band of
				compressed contone data in DRAM.
0x48	EndSourceAdr[21	19	0x0_0000	The 64-bit aligned word address
	:3]			containing the last bytes of the current
				band of compressed contone data in
				DRAM.
0x4C	ValidBytesLastFet	3	0x00	Indicates the number of valid bytes - 1
	ch	E		in the last 64-bit fetch of the current
				band of compressed contone data from
				DRAM. eg 0 implies bits 7:0 are valid, 1
				implies bits 15:0 are valid, 7 implies
				all 63:0 bits are valid etc.
JPEG deco	oder core setup registe	rs		
0x50	JpgDecMask	5	0x00	As segments are decoded they can
				also be output on the <i>DecJpg</i>
				(<i>JpgDecHdr</i>) port with the user
				selecting the segments for output by
				setting bits in the jpgDecMask port as

the input of CDU which feeds the JPEG
decoder core)
Bits 15-0 are JPEG decoder status
outputs from the CS6150 (see Table
for description of bits).

22.5.3 Typical operation

15

The CDU should only be started after the CFU has been started.

For the first band of data, users set up NextBandCurrSourceAdr, NextBandEndSourceAdr,
NextBandValidBytesLastFetch, and the various MaxPlane, MaxBlock, BuffStartBlockAdr,

BuffEndBlockAdr and NumBuffLines. Users then set the CDU's Go bit to start processing of the band. When the compressed contone data for the band has finished being read in, the cdu_finishedband interrupt will be sent to the PCU and CPU indicating that the memory associated with the first band is now free. Processing can now start on the next band of contone data.

- In order to process the next band NextBandCurrSourceAdr, NextBandEndSourceAdr and NextBandValidBytesLastFetch need to be updated before finally writing a 1 to NextBandEnable.

 There are 4 mechanisms for restarting the CDU between bands:
 - a. cdu_finishedband causes an interrupt to the CPU. The CDU will have set its DoneBand bit. The CPU reprograms the NextBandCurrSourceAdr, NextBandEndSourceAdr and NextBandValidBytesLastFetch registers, and sets NextBandEnable to restart the CDU.
 - b. The CPU programs the CDU's NextBandCurrSourceAdr, NextBandCurrEndAdr and Next-BandValidBytesLastFetch registers and sets the NextBandEnable bit before the end of the current band. At the end of the current band the CDU sets DoneBand. As NextBandEnable is already 1, the CDU starts processing the next band immediately.
- c. The PCU is programmed so that cdu_finishedband triggers the PCU to execute commands from DRAM to reprogram the NextBandCurrSourceAdr, NextBandEndSourceAdr and Next-BandValidBytesLastFetch registers and set the NextBandEnable bit to start the CDU processing the next band. The advantage of this scheme is that the CPU could process band headers in advance and store the band commands in DRAM ready for execution.
- d. This is a combination of b and c above. The PCU (rather than the CPU in b) programs the CDU's NextBandCurrSourceAdr, NextBandCurrEndAdr and NextBandValidBytesLastFetch registers and sets the NextBandEnable bit before the end of the current band. At the end of the current band the CDU sets DoneBand and pulses cdu_finishedband. As NextBandEnable is already 1, the CDU starts processing the next band immediately. Simultaneously, cdu_finishedband triggers the PCU to fetch commands from DRAM. The CDU will have restarted by the time the PCU has fetched commands from DRAM. The PCU commands program the CDU's next band shadow registers and sets the NextBandEnable bit.

If an error occurs in the JPEG stream, the JPEG decoder will suspend its operation, an error bit will be set in the *JpgDecStatus* register and the core will ignore any input data and await a reset before starting decoding again. An interrupt is sent to the CPU by asserting *cdu_icu_jpegerror* and the CDU should then be reset by means of a write to its *Reset* register before a new page can be printed.

22.5.4 Read control unit

5

10

15

20

25

40

The read control unit is responsible for reading the compressed contone data and passing it to the JPEG decoder via the FIFO. The compressed contone data is read from DRAM in single 256-bit accesses, receiving the data from the DIU over 4 clock cycles (64-bits per cycle). The protocol and timing for read accesses to DRAM is described in section 20.9.1 on page 240. Read accesses to DRAM are implemented by means of the state machine described in Figure 138. All counters and flags should be cleared after reset. When *Go* transitions from 0 to 1 all counters and flags should take their initial value. While the *Go* bit is set, the state machine relies on the *DoneBand* bit to tell it whether to attempt to read a band of compressed contone data. When *DoneBand* is set, the state machine does nothing. When *DoneBand* is clear, the state machine continues to load data into the JPEG input FIFO up to 256-bits at a time while there is space available in the FIFO. Note that the state machine has no knowledge about numbers of blocks or

continues to load data into the JPEG input FIFO up to 256-bits at a time while there is space available in the FIFO. Note that the state machine has no knowledge about numbers of blocks or numbers of color planes - it merely keeps the JPEG input FIFO full by consecutive reads from DRAM. The DIU is responsible for ensuring that DRAM requests are satisfied at least at the peak DRAM read bandwidth of 0.36 bits/cycle (see section 22.3 on page 329).

A modulo 4 counter, *rd_count*, is use to count each of the 64-bits received in a 256-bit read access. It is incremented whenever *diu_cdu_rvalid* is asserted. As each 64-bit value is returned, indicated by *diu_cdu_rvalid* being asserted, *curr_source_adr* is compared to both *end_source_adr* and *end_of_bandstore*:

- If {curr_source_adr,rd_count} equals end_source_adr, the end_of_band control signal sent to the FIFO is 1 (to signify the end of the band), the finishedCDUBand signal is output, and the DoneBand bit is set. The remaining 64-bit values in the burst from the DIU are ignored, i.e. they are not written into the FIFO.
- If rd_count equals 3 and {curr_source_adr,rd_count} does not equal end_source_adr, then

 curr_source_adr is updated to be either start_of_bandstore or curr_source_adr + 1,

 depending on whether curr_source_adr also equals end_of_bandstore. The end_of_band

 control signal sent to the FIFO is 0.

curr source adr is output to the DIU as cdu diu radr.

A count is kept of the number of 64-bit values in the FIFO. When diu_cdu_rvalid is 1 and ignore_data is 0, data is written to the FIFO by asserting FifoWr, and fifo_contents[3:0] and fifo_wr_adr[2:0] are both incremented.

When *fifo_contents*[3:0] is greater than 0, *jpg_in_strb* is asserted to indicate that there is data available in the FIFO for the JPEG decoder core. The JPEG decoder core asserts *jpg_in_rdy* when it is ready to receive data from the FIFO. Note it is also possible to bypass the JPEG decoder core by setting the *BypassJpg* register to 1. In this case data is sent directly from the

FIFO to the half-block double-buffer. While the JPEG decoder is not stalled (jpg_core_stall equal 0), and jpg_in_rdy (or $bypass_jpg$) and jpg_in_strb are both 1, a byte of data is consumed by the JPEG decoder core. $fifo_rd_adr[5:0]$ is then incremented to select the next byte. The read address is byte aligned, i.e. the upper 3 bits are input as the read address for the FIFO and the lower 3 bits are used to select a byte from the 64 bits. If $fifo_rd_adr[2:0] = 111$ then the next 64-bit value is read from the FIFO by asserting $fifo_rd$, and $fifo_contents[3:0]$ is decremented.

22.5.5 Compressed contone FIFO

5

30

35

The compressed contone FIFO conceptually is a 64-bit input, and 8-bit output FIFO to account for the 64-bit data transfers from the DIU, and the 8-bit requirement of the JPEG decoder.

- In reality, the FIFO is actually 8 entries deep and 65-bits wide (to accommodate two 256-bit accesses), with bits 63-0 carrying data, and bit 64 containing a 1-bit end_of_band flag. Whenever 64-bit data is written to the FIFO from the DIU, an end_of_band flag is also passed in from the read control unit. The end_of_band bit is 1 if this is the last data transfer for the current band, and 0 if it is not the last transfer. When end_of_band = 1 during an input, the ValidBytesLastFetch register is also copied to an image version of the same.
 - On the JPEG decoder side of the FIFO, the read address is byte aligned, i.e. the upper 3 bits are input as the read address for the FIFO and the lower 3 bits are used to select a byte from the 64 bits (1st byte corresponds to bits 7-0, second byte to bits 15-8 etc.). If bit 64 is set on the read, bits 63-0 contain the end of the bytestream for that band, and only the bytes specified by the
- image of *ValidBytesLastFetch* are valid bytes to be read and presented to the JPEG decoder.

 Note that *ValidBytesLastFetch* is copied to an image register as it may be possible for the CDU to be reprogrammed for the next band before the previous band's compressed contone data has been read from the FIFO (as an additional effect of this, the CDU has a non-problematic limitation in that each band of contone data must be more than 4 × 64-bits, or 32 bytes, in length).
- 25 22.5.6 CS6150 JPEG decoder
 - JPEG decoder functionality is implemented by means of a modified version of the Amphion CS6150 JPEG decoder core. The decoder is run at a nominal clock speed of 160 MHz. (Amphion have stated that the CS6150 JPEG decoder core can run at 185 MHz in 0.13um technology). The core is clocked by *jclk* which a gated version of the system clock pclk. Gating the clock provides a mechanism for stalling the JPEG decoder on a single color pixel-by-pixel basis. Control of the flow of output data is also provided by the *PixOutEnab* input to the JPEG decoder. However, this only allows stalling of the output at a JPEG block boundary and is insufficient for SoPEC. Thus gating of the clock is employed and *PixOutEnab* is instead tied high.
 - The CS6150 decoder automatically extracts all relevant parameters from the JPEG bytestream and uses them to control the decoding of the image. The JPEG bytestream contains data for the Huffman tables, quantization tables, restart interval definition and frame and scan headers. The decoder parses and checks the JPEG bytestream automatically detecting and processing all the JPEG marker segments. After identifying the JPEG segments the decoder re-directs the data to the appropriate units to be stored or processed as appropriate. Any errors detected in the

bytestream, apart from those in the entropy coded segments, are signalled and, if an error is found, the decoder stops reading the JPEG stream and waits to be reset.

JPEG images must have their data stored in interleaved format with no subsampling. Images longer than 65536 lines are allowed: these must have an initial imageHeight of 0. If the image has a Define Number Lines (DNL) marker at the end (normally necessary for standard JPEG, but not necessary for SoPEC's version of the CS6150), it must be equal to the total image height mod 64k or an error will be generated.

See the CS6150 Databook [21] for more details on how the core is used, and for timing diagrams of the interfaces. Note that [21] does not describe the use of the DNL marker in images of more than 64k lines length as this is a modification to the core.

The CS6150 decoder can be bypassed by setting the *BypassJpg* register. If this register is set, then the data read from DRAM must be in the same format as if it was produced by the JPEG decoder: 8x8 blocks of pixels in the correct color order. The data is uncompressed and is therefore lossless.

The following subsections describe the means by which the CS6150 internals can be made visible.

22.5.6.1 JPEG decoder reset

The JPEG decoder has 2 possible types of reset, an asynchronous reset and a synchronous clear. In SoPEC the asynchronous reset is connected to the hardware synchronous reset of the CDU and can be activated by any hardware reset to SoPEC (either from external pin or from any of the wake-up sources, e.g. USB activity, Wake-up register timeout) or by resetting the PEP section (*ResetSection* register in the CPR block).

The synchronous clear is connected to the software reset of the CDU and can be activated by the low to high transition of the *Go* register, or a software reset via the *Reset* register.

The 2 types of reset differ, in that the asynchronous reset, resets the JPEG core and causes the core to enter a memory initialization sequence that takes 384 clock cycles to complete after the reset is deasserted. The synchronous clear resets the core, but leaves the memory as is. This has some implications for programming the CDU.

In general the CDU should not be started (i.e. setting *Go* to 1) until at least 384 cycles after a hardware reset. If the CDU is started before then, the memory initialization sequence will be terminated leaving the JPEG core memory in an unknown state. This is allowed if the memory is to be initialized from the incoming JPEG stream.

22.5.6.2 JPEG decoder parameter bus

The decoding parameter bus *JpgDecPValue* is a 16-bit port used to output various parameters extracted from the input data stream and currently used by the core. The 4-bit selector input (*JpgDecPType*) determines which internal parameters are displayed on the parameter bus as per Table 148. The data available on the *PValue* port does not contain control signals used by the CS6150.

Table 148. Parameter bus definitions

	þ	NS: number of scan components in current scan, 1-4

22.5.6.3 JPEG decoder status register

5

10

15

The status register flags indicate the current state of the CS6150 operation. When an error is detected during the decoding process, the decompression process in the JPEG decoder is suspended and an interrupt is sent to the CPU by asserting <code>cdu_icu_jpegerror</code> (generated from <code>DecError</code>). The CPU can check the source of the error by reading the <code>JpgDecStatus register</code>. The CS6150 waits until a reset process is invoked by asserting the hard reset <code>prst_n</code> or by a soft reset of the CDU. The individual bits of <code>JpgDecStatus</code> are set to zero at reset and active high to indicate an error condition as defined in Table 149.

Note: A DecHfError will not block the input as the core will try to recover and produce the correct amount of pixel data. The DecHfError is cleared automatically at the start of the next image and so no intervention is required from the user. If any of the other errors occur in the decode mode then, following the error cancellation, the core will discard all input data until the next Start Of Image (SOI) without triggering any more errors.

The progress of the decoding can be monitored by observing the values of *TblDef*, *IDctInProg*, *DecInProg* and *JpgInProg*.

Table 149. JPEG decoder status register definitions

Bit	Name	Description					
15 - 12	TblDef[7:4]	Indicates the number of Huffman tables defined, 1bit/table.					
11 - 8	TblDef[3:0]	Indicates the number of quantization tables defined, 1bit/table.					
7	DecHfError	Set when an undefined Huffman table symbol is referenced during					
!		decoding.					
6	CtlError	Set when an invalid SOF parameter or an invalid SOS parameter is					
		detected.					
		Also set when there is a mismatch between the DNL segment input					
		to the core and the number of lines in the input image which have					
		already been decoded. Note that SoPEC's implementation of the					
		CS6150 does not require a final DNL when the initial setting for					
		ImageHeight is 0. This is to allow images longer than 64k lines.					
5	HtError	Set when an invalid DHT segment is detected.					
4	QtError	Set when an invalid DQT segment is detected.					
3 DecError	DecError	Set when anything other than a JPEG marker is input.					
	Set when any of DecFlags[6:4] are set.						
	Set when any data other than the SOI marker is detected at the						
		start of a stream.					
		Set when any SOF marker is detected other than SOF0. Set if					
	incomplete Huffman or quantization definition is detected.						
2 IDctinProg		Set when IDCT starts processing first data of a scan. Cleared when					
		IDCT has processed the last data of a scan.					
1	DecInProg	For each scan this signal is asserted after the SigSOS (Start of					
		Scan Segment) signal has been output from the core and is de-					
		asserted when the decoding of a scan is complete. It indicates that					
		the core is in the decoding state.					
0	JpgInProg	Set when core starts to process input data (JpgIn) and de-asserted					
		when decoding has been completed i.e. when the last pixel of last					
		block of the image is output.					

22.5.7 Half-block buffer interface

5

10

Since the CDU writes 256 bits (4 x 64 bits) to memory at a time, it requires a double-buffer of 2 x 256 bits at its output. This is implemented in an 8 x 64 bit FIFO. It is required to be able to stall the JPEG decoder core at its output on a half JPEG block boundary, i.e. after 32 pixels (8 bits per pixel). We provide a mechanism for stalling the JPEG decoder core by gating the clock to the core(with jclk_enable) when the FIFO is full. The output FIFO is responsible for providing two buffered half JPEG blocks to decouple JPEG decoding (read control unit) from writing those JPEG blocks to DRAM (write control unit). Data coming in is in 8-bit quantities but data going out is in 64-bit quantities for a single color plane.

22.5.8 Write control unit

5

40

A line of JPEG blocks in 4 colors, or 8 lines of decompressed contone data, is stored in DRAM with the memory arrangement as shown Figure 139. The arrangement is in order to optimize access for reads by writing the data so that 4 color components are stored together in each 256-bit DRAM word.

The CDU writes 8 lines of data in parallel but stores the first 4 lines and second 4 lines separately in DRAM. The write sequence for a single line of JPEG 8x8 blocks in 4 colors, as shown in Figure 139, is as follows below and corresponds to the order in which pixels are output from the JPEG decoder core:

10 block 0, color 0, line 0 in word p bits 63-0, line 1 in word p+1 bits 63-0, line 2 in word p+2 bits 63-0, line 3 in word p+3 bits 63-0, 15 block 0, color 0, line 4 in word q bits 63-0, line 5 in word q+1 bits 63-0, line 6 in word q+2 bits 63-0, line 7 in word q+3 bits 63-0, 20 block 0, color 1, line 0 in word p bits 127-64, line 1 in word p+1 bits 127-64, line 2 in word p+2 bits 127-64, line 3 in word p+3 bits 127-64, 25 block 0, color 1, line 4 in word q bits 127-64, line 5 in word q+1 bits 127-64, line 6 in word g+2 bits 127-64, line 7 in word q+3 bits 127-64, 30 repeat for block 0 color 2, block 0 color 3...... block 1, color 0, line 0 in word p+4 bits 63-0, line 1 in word p+5 bits 63-0, 35 etc.......... block N, color 3, line 4 in word q+4n bits 255-192, line 5

In SoPEC data is written to DRAM 256 bits at a time. The DIU receives a 64-bit aligned address from the CDU, i.e. the lower 2 bits indicate which 64-bits within a 256-bit location are being written to. With that address the DIU also receives half a JPEG block (4 lines) in a single color, 4 x 64 bits

192, line 7 in word q+4n+3 bit 255-192

line 6 in word q+4n+2 bits 255-

in word q+4n+1 bits 255-192,

over 4 cycles. All accesses to DRAM must be padded to 256 bits or the bits which should not be written are masked using the individual bit write inputs of the DRAM. When writing decompressed contone data from the CDU, only 64 bits out of the 256-bit access to DRAM are valid, and the remaining bits of the write are masked by the DIU. This means that the decompressed contone data is written to DRAM in 4 back-to-back 64-bit write masked accesses to 4 consecutive 256-bit DRAM locations/words.

5

10

15

20

25

Writing of decompressed contone data to DRAM is implemented by the state machine in Figure 140. The CDU writes the decompressed contone data to DRAM half a JPEG block at a time, 4 x 64 bits over 4 cycles. All counters and flags should be cleared after reset. When Go transitions from 0 to 1 all counters and flags should take their initial value. While the Go bit is set, the state machine relies on the half_block_ok_to_read and line_store_ok_to_write flags to tell it whether to attempt to write a half JPEG block to DRAM. Once the half-block buffer interface contains a half JPEG block, the state machine requests a write access to DRAM by asserting cdu_diu_wreq and providing the write address, corresponding to the first 64-bit value to be written, on cdu_diu_wadr (only the address the first 64-bit value in each access of 4x64 bits is issued by the CDU. The DIU can generate the addresses for the second, third and fourth 64-bit values). The state machine then waits to receive an acknowledge from the DIU before initiating a read of 4 64-bit values from the half-block buffer interface by asserting rd_adv for 4 cycles. The output cdu_diu_wvalid is asserted in the cycle after rd_adv to indicate to the DIU that valid data is present on the cdu_diu_data bus and should be written to the specified address in DRAM. A rd_adv_half_block pulse is then sent to the half-block buffer interface to indicate that the current read buffer has been read and should now be available to be written to again. The state machine then returns to the request state.

The pseudocode below shows how the write address is calculated on a per clock cycle basis. Note counters and flags should be cleared after reset. When *Go* transitions from 0 to 1 all counters and flags should be cleared and *lwr_halfblock_adr* gets loaded with *buff_start_adr* and *upr_halfblock_adr* gets loaded with *buff_start_adr* + *max_block* + 1.

```
// assign write address output to DRAM
30
                                       = 00
                   cdu diu wadr[6:5]
                                                          // corresponds to
                 linenumber, only first address is
                                                  // issued for each DRAM
                 access. Thus line is always 0.
                                                  // The DIU generates these
35
                 bits of the address.
                   cdu diu wadr[4:3] = color
                   if (half == 1) then
                     cdu_diu_wadr[21:7] = upr_halfblock_adr  // for lines
40
                 4-7 of JPEG block
                   else
```

```
cdu_diu_wadr[21:7] = lwr_halfblock_adr  // for lines
                0-3 of JPEG block
                // update half, color, block and addresses after each DRAM
5
                write access

22.5.9 Contone line store interface

15

20

25

30

35

The contone line store interface is responsible for providing the control over the shared resource in DRAM. The CDU writes 8 lines of data in up to 4 color planes, and the CFU reads them line-at-a-time. The contone line store interface provides the mechanism for keeping track of the number of lines stored in DRAM, and provides signals so that a given line cannot be read from until the complete line has been written.

The CDU writes 8 lines of data in parallel but writes the first 4 lines and second 4 lines to separate areas in DRAM. Thus, when the CFU has read 4 lines from DRAM that area now becomes free for the CDU to write to. Thus the size of the line store in DRAM should be a multiple of 4 lines. The minimum size of the line store interface is 8 lines, providing a single buffer scheme. Typical sizes are 12 lines for a 1.5 buffer scheme while 16 lines provides a double-buffer scheme. The size of the contone line store is defined by num_buff_lines . A count is kept of the number of lines stored in DRAM that are available to be written to. When Go transitions from 0 to 1,

NumLinesAvail is set to the value of num_buff_lines. The CDU may only begin to write to DRAM as long as there is space available for 8 lines, indicated when the line_store_ok_to_write bit is set. When the CDU has finished writing 8 lines, the write control unit sends an wradv8line pulse to the contone line store interface, and NumLinesAvail is decremented by 8. The write control unit then waits for line_store_ok_to_write to be set again.

If the contone line store is not empty (has one or more lines available in it), the CDU will indicate to the CFU via the <code>cdu_cfu_linestore_rdy</code> signal. The <code>cdu_cfu_linestore_rdy</code> signal is generated by comparing the <code>NumLinesAvail</code> with the programmed <code>num_buff_lines</code>. As the CFU reads a line from the contone line store it will pulse the <code>rdadvline</code> to indicate that it has read a full line from the line store. <code>NumLinesAvail</code> is incremented by 1 on receiving a <code>rdadvline</code> pulse.

To enable running the CDU while the CFU is not running the *NumLinesAvail* register can also be updated via the configuration register interface. In this scenario the CPU polls the value of the *NumLinesAvail* register and overwrites it to prevent stalling of the CDU (*NumLinesAvail* < 8). The CPU will always have priority in any updating of the *NumLinesAvail* register.

- 40 23 Contone FIFO Unit (CFU)
 - 23.1 OVERVIEW

The Contone FIFO Unit (CFU) is responsible for reading the decompressed contone data layer from the circular buffer in DRAM, performing optional color conversion from YCrCb to RGB followed by optional color inversion in up to 4 color planes, and then feeding the data on to the HCU. Scaling of data is performed in the horizontal and vertical directions by the CFU so that the output to the HCU matches the printer resolution. Non-integer scaling is supported in both the horizontal and vertical directions. Typically, the scale factor will be the same in both directions but may be programmed to be different.

23.2 BANDWIDTH REQUIREMENTS

5

10

15

35

The CFU must read the contone data from DRAM fast enough to match the rate at which the contone data is consumed by the HCU.

Pixels of contone data are replicated a X scale factor (SF) number of times in the X direction and Y scale factor (SF) number of times in the Y direction to convert the final output to 1600 dpi. Replication in the X direction is performed at the output of the CFU on a pixel-by-pixel basis while replication in the Y direction is performed by the CFU reading each line a number of times, according to the Y-scale factor, from DRAM. The HCU generates 1 dot (bi-level in 6 colors) per system clock cycle to achieve a print speed of 1 side per 2 seconds for full bleed A4/Letter printing. The CFU output buffer needs to be supplied with a 4 color contone pixel (32 bits) every SF cycles. With support for 4 colors at 267 ppi the CFU must read data from DRAM at 5.33 bits/cycle¹⁴.

20 23.3 COLOR SPACE CONVERSION

The CFU allows the contone data to be passed directly on, which will be the case if the color represented by each color plane in the JPEG image is an available ink. For example, the four colors may be C, M, Y, and K, directly represented by CMYK inks. The four colors may represent gold, metallic green etc. for multi-SoPEC printing with exact colors.

- JPEG produces better compression ratios for a given visible quality when luminance and chrominance channels are separated. With CMYK, K can be considered to be luminance, but C, M and Y each contain luminance information and so would need to be compressed with appropriate luminance tables. We therefore provide the means by which CMY can be passed to SoPEC as YCrCb. K does not need color conversion.
- When being JPEG compressed, CMY is typically converted to RGB, then to YCrCb and then finally JPEG compressed. At decompression, the YCrCb data is obtained, then color converted to RGB, and finally back to CMY.

The external RIP provides conversion from RGB to YCrCb, specifically to match the actual hardware implementation of the inverse transform within SoPEC, as per CCIR 601-2 [24] except that Y, Cr and Cb are normalized to occupy all 256 levels of an 8-bit binary encoding.

¹⁴32 bits / 6 cycles = 5.33 bits/cycle

The CFU provides the translation to either RGB or CMY. RGB is included since it is a necessary step to produce CMY, and some printers increase their color gamut by including RGB inks as well as CMYK.

Consequently the JPEG stream in the color space convertor is one of:

- 5 1 color plane, no color space conversion
 - 2 color planes, no color space conversion
 - 3 color planes, no color space conversion
 - 3 color planes YCrCb, conversion to RGB
 - 4 color planes, no color space conversion
- 4 color planes YCrCbX, conversion of YCrCb to RGB, no color conversion of X

The YCrCb to RGB conversion is described in [14]. Note that if the data is non-compressed, there is no specific advantage in performing color conversion (although the CDU and CFU do permit it).

23.4 COLOR SPACE INVERSION

In addition to performing optional color conversion the CFU also provides for optional bit-wise inversion in up to 4 color planes. This provides the means by which the conversion to CMY may be finalised, or to may be used to provide planar correlation of the dither matrices.

The RGB to CMY conversion is given by the relationship:

- C = 255 R
- M = 255 G
- 20 Y = 255 B

15

30

These relationships require the page RIP to calculate the RGB from CMY as follows:

- R = 255 C
- G = 255 M
- B = 255 Y
- 25 23.5 SCALING

Scaling of pixel data is performed in the horizontal and vertical directions by the CFU so that the output to the HCU matches the printer resolution. The CFU supports non-integer scaling with the scale factor represented by a numerator and a denominator. Only scaling up of the pixel data is allowed, i.e. the numerator should be greater than or equal to the denominator. For example, to scale up by a factor of two and a half, the numerator is programmed as 5 and the denominator programmed as 2.

Scaling is implemented using a counter as described in the pseudocode below. An advance pulse is generated to move to the next dot (x-scaling) or line (y-scaling).

23.6 LEAD-IN AND LEAD-OUT CLIPPING

The JPEG algorithm encodes data on a block by block basis, each block consists of 64 8-bit pixels (representing 8 rows each of 8 pixels). If the image is not a multiple of 8 pixels in X and Y then padding must be present. This padding (extra pixels) will be present after decoding of the JPEG bytestream.

5 Extra padded lines in the Y direction (which may get scaled up in the CFU) will be ignored in the HCU through the setting of the *BottomMargin* register.

Extra padded pixels in the X direction must also be removed so that the contone layer is clipped to the target page as necessary.

In the case of a multi-SoPEC system, 2 SoPECs may be responsible for printing the same side of a page, e.g. SoPEC #1 controls printing of the left side of the page and SoPEC #2 controls printing of the right side of the page and shown in Figure 141. The division of the contone layer between the 2 SoPECs may not fall on a 8 pixel (JPEG block) boundary. The JPEG block on the boundary of the 2 SoPECs (JPEG block n below) will be the last JPEG block in the line printed by SoPEC #1 and the first JPEG block in the line printed by SoPEC #2. Pixels in this JPEG block not destined for SoPEC #1 are ignored by appropriately setting the LeadOutClipNum. Pixels in this JPEG block not destined for SoPEC #2 must be ignored at the beginning of each line. The number of pixels to be ignored at the start of each line is specified by the LeadInClipNum register. It may also be the case that the CDU writes out more JPEG blocks than is required to be read by the CFU, as shown for SoPEC #2 below. In this case the value of the MaxBlock register in the CDU is set to correspond to JPEG block m but the value for the MaxBlock register in the CFU is set to correspond to JPEG block m-1. Thus JPEG block m is not read in by the CFU. Additional clipping on contone pixels is required when they are scaled up to the printer's resolution. The scaling of the first valid pixel in the line is controlled by setting the XstartCount register. The HcuLineLength register defines the size of the target page for the contone layer at the printer's resolution and controls the scaling of the last valid pixel in a line sent to the HCU.

23.7 IMPLEMENTATION

Figure 142 shows a block diagram of the CFU.

23.7.1 Definitions of I/O

Table 150. CFU port list and description

30

10

15

20

25

Port Name	Pins	1/0	Description	
Clocks and reset				
pclk	1	In	System clock	
prst_n	1	ln	System reset, synchronous active low.	
PCU interface		<u></u>	<u> </u>	
pcu_cfu_sel	1	ln	Block select from the PCU. When pcu_cfu_sel is high both pcu_adr and pcu_dataout are valid.	
pcu_rwn	1	In	Common read/not-write signal from the PCU.	
pcu_adr[6:2]	4	4 In PCU address bus. Only 5 bits are required to		

		T	decode the address space for this block.
dot 4[24.0]	22	1	
pcu_dataout[31:0]	32	ln .	Shared write data bus from the PCU.
cfu_pcu_rdy	1	Out	Ready signal to the PCU. When cfu_pcu_rdy is high
			it indicates the last cycle of the access. For a write
			cycle this means pcu_dataout has been registered
			by the block and for a read cycle this means the data
			on cfu_pcu_datain is valid.
cfu_pcu_datain[31:0]	32	Out	Read data bus to the PCU.
DIU interface			
cfu_diu_rreq	1	Out	CFU read request, active high. A read request must
			be accompanied by a valid read address.
diu_cfu_rack	1	ln	Acknowledge from DIU, active high. Indicates that a
			read request has been accepted and the new read
			address can be placed on the address bus,
			cfu_diu_radr.
cfu_diu_radr[21:5]	17	Out	CFU read address. 17 bits wide (256-bit aligned
			word).
diu_cfu_rvalid	1	ln	Read data valid, active high. Indicates that valid read
			data is now on the read data bus, diu_data.
diu_data[63:0]	64	ln	Read data from DRAM.
CDU interface	1		
cdu_cfu_linestore_rdy	/1	ln	When high indicates that the contone line store has 1
			or more lines available to be read by the CFU.
cfu_cdu_rdadvline	1	Out	Read line pulse, active high. Indicates that the CFU
			has finished reading a line of decompressed contone
			data to the circular buffer in DRAM and that line of
			the buffer is now free.
HCU interface			
hcu_cfu_advdot	1	ln	Informs the CFU that the HCU has captured the pixel
			data on cfu_hcu_c[0-3]data lines and the CFU can
			now place the next pixel on the data lines.
cfu_hcu_avail	1	Out	Indicates valid data present on cfu_hcu_c[0-3]data
			lines.
cfu_hcu_c0data[7:0]	8	Out	Pixel of data in contone plane 0.
cfu_hcu_c1data[7:0]	8	Out	Pixel of data in contone plane 1.
cfu_hcu_c2data[7:0]	8	Out	Pixel of data in contone plane 2.
cfu_hcu_c3data[7:0]	8	Out	Pixel of data in contone plane 3.
			<u> </u>

23.7.2 Configuration registers

The configuration registers in the CFU are programmed via the PCU interface. Refer to section 21.8.2 on page 321 for the description of the protocol and timing diagrams for reading and writing registers in the CFU. Note that since addresses in SoPEC are byte aligned and the PCU only supports 32-bit register reads and writes, the lower 2 bits of the PCU address bus are not required to decode the address space for the CFU. When reading a register that is less than 32 bits wide zeros should be returned on the upper unused bit(s) of *cfu_pcu_datain*. The configuration registers of the CFU are listed in Table 151:

Table 151. CFU registers

5

Address	Register Name	#bits	Value	Description
(CFU_base +)			on	
			Reset	
Control registers	S	L	1	
0x00	Reset	1	0x1	A write to this register causes a reset of
				the CFU.
0x04	Go	1	0x0	Writing 1 to this register starts the CFU.
				Writing 0 to this register halts the CFU.
			!	When <i>Go</i> is deasserted the state-
				machines go to their idle states but all
				counters and configuration registers
				keep their values.
				When <i>Go</i> is asserted all counters are
				reset, but configuration registers keep
				their values (i.e. they don't get reset).
				The CFU must be started before the
				CDU is started.
				This register can be read to determine
				if the CFU is running
				(1 - running, 0 - stopped).
Setup registers				
0x10	MaxBlock	13	0x000	Number of JPEG MCUs (or JPEG
				block equivalents, i.e. 8x8 bytes) in a
				line - 1.
0x14	BuffStartAdr[21:7]	15	0x0000	Points to the start of the decompressed
				contone circular buffer in DRAM,
				aligned to a half JPEG block boundary.
				A half JPEG block consists of 4 words
				of 256-bits, enough to hold 32 contone
				pixels in 4 colors, i.e. half a JPEG

		Γ		block.
0x18	BuffEndAdr[21:7]	15	0x0000	Points to the end of the decompressed contone circular buffer in DRAM, aligned to a half JPEG block boundary (address is inclusive). A half JPEG block consists of 4 words of 256-bits, enough to hold 32 contone pixels in 4 colors, i.e. half a JPEG block.
0x1C	4LineOffset	13	0x0000	Defines the offset between the start of one 4 line store to the start of the next 4 line store - 1. In Figure in page 394 on page Error! Bookmark not defined., if BufStartAdr corresponds to line 0 block 0 then BuffStartAdr + 4LineOffset corresponds to line 4 block 0. 4LineOffset is specified in units of128 bytes, eg 0 - 128 bytes,1 - 256 bytes etc. This register is required in addition to MaxBlock as the number of JPEG blocks in a line required by the CFU may be different from the number of JPEG blocks in a line written by the CDU.
0x20	YCrCb2RGB	1	0x0	Set this bit to enable conversion from YCrCb to RGB. Should not be changed between bands.
0x24	InvertColorPlane	4	0x0	Set these bits to perform bit-wise inversion on a per color plane basis. bit0 - 1 invert color plane 0 - 0 do not convert bit1 - 1 invert color plane 1 - 0 do not convert bit2 - 1 invert color plane 2 - 0 do not convert bit3 - 1 invert color plane 3 Should not be changed between bands.

	16	0x0000	Number of contone pixels - 1 in a line
			(after scaling). Equals the number of
			hcu_cfu_dotadv pulses - 1 received
			from the HCU for each line of contone
			data.
LeadInClipNum	3	0x0	Number of contone pixels to be ignored
			at the start of a line (from JPEG block 0
			in a line). They are not passed to the
			output buffer to be scaled in the X
			direction.
LeadOutClipNum	3	0x0	Number of contone pixels to be ignored
			at the end of a line (from JPEG block
			MaxBlock in a line). They are not
			passed to the output buffer to be scaled
			in the X direction.
XstartCount	8	0x00	Value to be loaded at the start of every
			line into the counter used for scaling in
			the X direction. Used to control the
			scaling of the first pixel in a line to be
			sent to the HCU.
		,	This value will typically be zero, except
			in the case where a number of dots are
			clipped on the lead in to a line.
XscaleNum	8	0x01	Numerator of contone scale factor in X
			direction.
XscaleDenom	8	0x01	Denominator of contone scale factor in
			X direction.
YscaleNum	8	0x01	Numerator of contone scale factor in Y
			direction.
YscaleDenom	8	0x01	Denominator of contone scale factor in
	LeadOutClipNum XstartCount XscaleNum XscaleDenom YscaleNum	LeadOutClipNum 3 XstartCount 8 XscaleNum 8 XscaleDenom 8 YscaleNum 8	LeadOutClipNum 3 0x0 XstartCount 8 0x00 XscaleNum 8 0x01 XscaleDenom 8 0x01 YscaleNum 8 0x01

23.7.3 Storage of decompressed contone data in DRAM

5

The CFU reads decompressed contone data from DRAM in single 256-bit accesses. JPEG blocks of decompressed contone data are stored in DRAM with the memory arrangement as shown The arrangement is in order to optimize access for reads by writing the data so that 4 color components are stored together in each 256-bit DRAM word. The means that the CFU reads 64-bits in 4 colors from a single line in each 256-bit DRAM access.

The CFU reads data line at a time in 4 colors from DRAM. The read sequence, as shown in Figure 143, is as follows:

```
line 0, block 0 in word p of DRAM
line 0, block 1 in word p+4 of DRAM
.....
line 0, block n in word p+4n of DRAM
(repeat to read line a number of times according to scale factor)
line 1, block 0 in word p+1 of DRAM
```

line 1, block 1 in word p+5 of DRAM
etc.....

The CFU reads a complete line in up to 4 colors a Y scale factor number of times from DRAM before it moves on to read the next. When the CFU has finished reading 4 lines of contone data that 4 line store becomes available for the CDU to write to.

23.7.4 Decompressed contone buffer

10

35

40

Since the CFU reads 256 bits (4 colors x 64 bits) from memory at a time, it requires storage of at least 2 x 256 bits at its input. To allow for all possible DIU stall conditions the input buffer is increased to 3 x 256 bits to meet the CFU target bandwidth requirements. The CFU receives the data from the DIU over 4 clock cycles (64-bits of a single color per cycle). It is implemented as 4 buffers. Each buffer conceptually is a 64-bit input and 8-bit output buffer to account for the 64-bit data transfers from the DIU, and the 8-bit output per color plane to the color space converter. On the DRAM side, wr_buff indicates the current buffer within each triple-buffer that writes are to occur to. wr_sel selects which triple-buffer to write the 64 bits of data to when wr_en is asserted. On the color space converter side, rd_buff indicates the current buffer within each triple-buffer that reads are to occur from. When rd_en is asserted a byte is read from each of the triple-buffers in parallel. rd_sel is used to select a byte from the 64 bits (1st byte corresponds to bits 7-0, second byte to bits 15-8 etc.).

Due to the limitations of available register arrays in IBM technology, the decompressed contone buffer is implemented as a quadruple buffer. While this offers some benefits for the CFU it is not necessitated by the bandwidth requirements of the CFU.

30 23.7.5 Y-scaling control unit

The Y-scaling control unit is responsible for reading the decompressed contone data and passing it to the color space converter via the decompressed contone buffer. The decompressed contone data is read from DRAM in single 256-bit accesses, receiving the data from the DIU over 4 clock cycles (64-bits per cycle). The protocol and timing for read accesses to DRAM is described in section 20.9.1 on page 240. Read accesses to DRAM are implemented by means of the state machine described in Figure 144.

All counters and flags should be cleared after reset. When Go transitions from 0 to 1 all counters and flags should take their initial value. While the Go bit is set, the state machine relies on the line8_ok_to_read and buff_ok_to_write flags to tell it whether to attempt to read a line of compressed contone data from DRAM. When line8_ok_to_read is 0 the state machine does

nothing. When *line8_ok_to_read* is 1 the state machine continues to load data into the decompressed contone buffer up to 256-bits at a time while there is space available in the buffer. A bit is kept for the status of each 64-bit buffer: *buff_avail[0]* and *buff_avail[1]*. It also keeps a single bit (*rd_buff*) for the current buffer that reads are to occur from, and a single bit (*wr_buff*) for the current buffer that writes are to occur to.

5

10

15

buff_ok_to_write equals ~buff_avail[wr_buff]. When a wr_adv_buff pulse is received, buff_avail[wr_buff] is set, and wr_buff is inverted. Whenever diu_cfu_rvalid is asserted, wr_en is asserted to write the 64-bits of data from DRAM to the buffer selected by wr_sel and wr_buff.

buff_ok_to_read equals buff_avail[rd_buff]. If there is data available in the buffer and the output double-buffer has space available (outbuff_ok_to_write equals 1) then data is read from the buffer by asserting rd_en and rd_sel gets incremented to point to the next value. wr_adv is asserted in the following cycle to write the data to the output double-buffer of the CFU. When finished reading the buffer, rd_sel equals b111 and rd_en is asserted, buff_avail[rd_buff] is set, and rd_buff is inverted.

Each line is read a number of times from DRAM, according to the Y-scale factor, before the CFU moves on to start reading the next line of decompressed contone data. Scaling to the printhead resolution in the Y direction is thus performed.

The pseudocode below shows how the read address from DRAM is calculated on a per clock cycle basis. Note all counters and flags should be cleared after reset or when *Go* is cleared. When a 1 is written to *Go*, both *curr_halfblock* and *line_start_halfblock* get loaded with *buff_start_adr*, and *y_scale_count* gets loaded with *y_scale_denom*. Scaling in the Y direction is implemented by line replication by re-reading lines from DRAM. The algorithm for non-integer scaling is described in the pseudocode below.

```
// assign read address output to DRAM
                   cdu diu wadr[21:7] = curr halfblock
                   cdu_diu_wadr[6:5] = line[1:0]
30
                 // update block, line, y_scale_count and addresses after
                 each DRAM read access
                   if (wr_adv_buff == 1) then
                                                    // end of reading a line
                     if (block == max block) then
35
                 of contone in up to 4 colors
                        block = 0
                        // check whether to advance to next line of contone
                 data in DRAM
                        if (y_scale_count + y_scale_denom - y_scale_num >= 0)
40
                 then
                            y_scale_count = y_scale_count + y_scale_denom -
                 y scale num
```

```
pulse RdAdvline
                                                      // end of reading 4 line
                           if (line == 3) then
                 store of contone data
 5
                               // update half block address for start of next
                 line taking account of
                               // address wrapping in circular buffer and 4
                 line offset
                               if (curr halfblock == buff end adr) then
10
                                    curr halfblock = buff start adr

23.7.6 Contone line store interface

35

40

The contone line store interface is responsible for providing the control over the shared resource in DRAM. The CDU writes 8 lines of data in up to 4 color planes, and the CFU reads them line-at-a-time. The contone line store interface provides the mechanism for keeping track of the number of lines stored in DRAM, and provides signals so that a given line cannot be read from until the complete line has been written.

A count is kept of the number of lines that have been written to DRAM by the CDU and are available to be read by the CFU. At start-up, <code>buff_lines_avail</code> is set to the 0. The CFU may only begin to read from DRAM when the CDU has written 8 complete lines of contone data. When the CDU has finished writing 8 lines, it sends an <code>cdu_cfu_wradv8line</code> pulse to the CFU, and <code>buff_lines_avail</code> is incremented by 8. The CFU may continue reading from DRAM as long as <code>buff_lines_avail</code> is greater than 0. <code>line8_ok_to_read</code> is set while <code>buff_lines_avail</code> is greater than 0. When it has completely finished reading a line of contone data from DRAM, the Y-scaling control

unit sends a *RdAdvLine* signal to contone line store interface and to the CDU to free up the line in the buffer in DRAM. *buff_lines_avail* is decremented by 1 on receiving a *RdAdvline* pulse.

23.7.7 Color Space Converter (CSC)

5

15

30

The color space converter consists of 2 stages: optional color conversion from YCrCb to RGB followed by optional bit-wise inversion in up to 4 color planes.

The convert YCrCb to RGB block takes 3 8-bit inputs defined as Y, Cr, and Cb and outputs either the same data YCrCb or RGB. The YCrCb2RGB parameter is set to enable the conversion step from YCrCb to RGB. If YCrCb2RGB equals 0, the conversion does not take place, and the input pixels are passed to the second stage. The 4th color plane, if present, bypasses the convert

10 YCrCb to RGB block. Note that the latency of the convert YCrCb to RGB block is 1 cycle. This latency should be equalized for the 4th color plane as it bypasses the block.

The second stage involves optional bit-wise inversion on a per color plane basis under the control of *invert_color_plane*. For example if the input is YCrCbK, then *YCrCb2RGB* can be set to 1 to convert YCrCb to RGB, and *invert_color_plane* can be set to 0111 to then convert the RGB to CMY, leaving K unchanged.

If YCrCb2RGB equals 0 and invert_color_plane equals 0000, no color conversion or color inversion will take place, so the output pixels will be the same as the input pixels.

Figure 145 shows a block diagram of the color space converter.

The convert YCrCb to RGB block is an implementation of [14]. Although only 10 bits of coefficients are used (1 sign bit, 1 integer bit, 8 fractional bits), full internal accuracy is maintained with 18 bits. The conversion is implemented as follows:

- R* = Y + (359/256)(Cr-128)
- G* = Y (183/256)(Cr-128) (88/256)(Cb-128)
- $B^* = Y + (454/256)(Cb-128)$
- R*, G* and B* are rounded to the nearest integer and saturated to the range 0-255 to give R, G and B. Note that, while a *Reset* results in all-zero output, a zero input gives output RGB = $[0^{15}, 136^{16}, 0^{17}]$.

23.7.8 X-scaling control unit

The CFU has a 2 x 32-bit double-buffer at its output between the color space converter and the HCU. The X-scaling control unit performs the scaling of the contone data to the printers output resolution, provides the mechanism for keeping track of the current read and write buffers, and ensures that a buffer cannot be read from until it has been written to.

¹⁵-179 is saturated to 0

¹⁶135.5, with rounding becomes 136.

¹⁷-227 is saturated to 0

A bit is kept for the status of each 32-bit buffer: buff_avail[0] and buff_avail[1]. It also keeps a single bit (rd_buff) for the current buffer that reads are to occur from, and a single bit (wr_buff) for the current buffer that writes are to occur to.

The output value *outbuff_ok_to_write* equals ~*buff_avail[wr_buff]*. Contone pixels are counted as they are received from the Y-scaling control unit, i.e. when *wr_adv* is 1. Pixels in the lead-in and lead-out areas are ignored, i.e. they are not written to the output buffer. Lead-in and lead-out clipping of pixels is implemented by the following pseudocode that generates the *wr_en* pulse for the output buffer.

5

25

30

When a *wr_en* pulse is sent to the output double-buffer, *buff_avail[wr_buff]* is set, and *wr_buff* is inverted

The output cfu_hcu_avail equals $buff_avail[rd_buff]$. When cfu_hcu_avail equals 1, this indicates to the HCU that data is available to be read from the CFU. The HCU responds by asserting hcu_cfu_advdot to indicate that the HCU has captured the pixel data on $cfu_hcu_c[0-3]data$ lines and the CFU can now place the next pixel on the data lines.

The input pixels from the CSC may be scaled a non-integer number of times in the X direction to produce the output pixels for the HCU at the printhead resolution. Scaling is implemented by pixel replication. The algorithm for non-integer scaling is described in the pseudocode below. Note,

x_scale_count should be loaded with x_start_count after reset and at the end of each line. This controls the amount by which the first pixel is scaled by. hcu_line_length and hcu_cfu_dotadv control the amount by which the last pixel in a line that is sent to the HCU is scaled by.

When a rd_en pulse is received, buff_avail[rd_buff] is cleared, and rd_buff is inverted.

A 16-bit counter, dot_adv_count, is used to keep a count of the number of hcu_cfu_dotadv pulses received from the HCU. If the value of dot_adv_count equals hcu_line_length and a hcu_cfu_dotadv pulse is received, then a rd_en pulse is genrated to present the next dot at the output of the CFU, dot_adv_count is reset to 0 and x_scale_count is loaded with x_start_count.

24 Lossless Bi-level Decoder (LBD)

24.1 OVERVIEW

The Lossless Bi-level Decoder (LBD) is responsible for decompressing a single plane of bi-level data. In SoPEC bi-level data is limited to a single spot color (typically black for text and line graphics).

The input to the LBD is a single plane of bi-level data, read as a bitstream from DRAM. The LBD is programmed with the start address of the compressed data, the length of the output

- (decompressed) line, and the number of lines to decompress. Although the requirement for SoPEC is to be able to print text at 10:1 compression, the LBD can cope with any compression ratio if the requested DRAM access is available. A pass-through mode is provided for 1:1 compression. Ten-point plain text compresses with a ratio of about 50:1. Lossless bi-level compression across an average page is about 20:1 with 10:1 possible for pages which compress poorly.
 - The output of the LBD is a single plane of decompressed bi-level data. The decompressed bi-level data is output to the SFU (Spot FIFO Unit), and in turn becomes an input to the HCU (Halftoner/Compositor unit) for the next stage in the printing pipeline. The LBD also outputs a <code>lbd_finishedband</code> control flag that is used by the PCU and is available as an interrupt to the CPU.
- 25 24.2 Main Features of LBD

Figure 147 shows a schematic outline of the LBD and SFU.

The LBD is required to support compressed images of up to 800 dpi. If possible we would like to support bi-level images of up to 1600 dpi. The line buffers must therefore be long enough to store a complete line at 1600 dpi.

- The PEC1 LBD is required to output 2 dots/cycle to the HCU. This throughput capability is retained for SoPEC to minimise changes to the block, although in SoPEC the HCU will only read 1 dot/cycle. The PEC1 LDB outputs 16 bits in parallel to the PEC1 spot buffer. This is also retained for SoPEC. Therefore the LBD in SoPEC can run much faster than is required. This is useful for allowing stalls, e.g. due to band processing latency, to be absorbed.
- The LBD has a pass through mode to cope with local negative compression. Pass through mode is activated by a special run-length code. Pass through mode continues to either end of line or for a pre-programmed number of bits, whichever is shorter. The special run-length code is always executed as a run-length code, followed by pass through.

The LBD outputs decompressed bi-level data to the NextLineFIFO in the Spot FIFO Unit (SFU).

40 This stores the decompressed lines in DRAM, with a typical minimum of 2 lines stored in DRAM,

nominally 3 lines up to a programmable number of lines. The SFU's *NextLineFIFO* can fill while the SFU waits for write access to DRAM. Therefore the LBD must be able to support stalling at its output during a line.

The LBD uses the previous line in the decoding process. This is provided by the SFU via it's PrevLineFIFO. Decoding can stall in the LBD while this FIFO waits to be filled from DRAM.

A signal *sfu_ldb_rdy* indicates that both the SFU's *NextLineFIFO* and *PrevLineFIFO* are available for writing and reading, respectively.

A configuration register in the LBD controls whether the first line being decoded at the start of a band uses the previous line read from the SFU or uses an all 0's line instead.

The line length is stored in DRAM must be programmable to a value greater than 128. An A4 line of 13824 dots requires 1.7Kbytes of storage. An A3 line of 19488 dots requires 2.4 Kbytes of storage.

The compressed spot data can be read at a rate of 1 bit/cycle for pass through mode 1:1 compression.

The LBD finished band signal is exported to the PCU and is additionally available to the CPU as an interrupt.

24.2.1 Bi-level Decoding in the LBD

5

20

25

The black bi-level layer is losslessly compressed using Silverbrook Modified Group 4 (SMG4) compression which is a version of Group 4 Facsimile compression [22] without Huffman and with simplified run length encodings. The encoding are listed in Table 152 and Table 153.

Table 152. Bi-Level group 4 facsimile style compression encodings

	Encoding	Description
same as Group 4 Facsimile	1000	Pass Command: a0 ← b2, skip next two edges
··· -·	1	Vertical(0): a0 ← b1, color = !color
	110	Vertical(1): a0 ← b1 + 1, color = !color
	010	Vertical(-1): a0 ← b1 - 1, color = !color
	110000	Vertical(2): a0 ← b1 + 2, color = !color
	010000	Vertical(-2): a0 ← b1 - 2, color = !color
Unique to this	100000	Vertical(3): a0 ← b1 + 3, color = !color
implementation		
	000000	Vertical(-3): a0 ← b1 - 3, color = !color
	<rl><rl>10</rl></rl>	Horizontal: a0 ← a0 + <rl> + <rl></rl></rl>
	o	

SMG4 has a pass through mode to cope with local negative compression. Pass through mode is activated by a special run-length code. Pass through mode continues to either end of line or for a pre-programmed number of bits, whichever is shorter. The special run-length code is always executed as a run-length code, followed by pass through. The pass through escape code is a medium length run-length with a run of less than or equal to 31.

Table 153. Run length (RL) encodings

		Encoding	Description
Unique implemen	to itation	 RRRRR1	Short Black Runlength (5 bits)
		 RRRRR1	Short White Runlength (5 bits)
		RRRRRRRRR10	Medium Black Runlength (10 bits)
		RRRRRRRR10	Medium White Runlength (8 bits)
			Medium Black Runlength with RRRRRRRRRR <= 31, Enter pass through
		RRRRRRR10	Medium White Runlength with RRRRRRRR <= 31, Enter pass through
		RRRRRRRRRRR RR00	Long Black Runlength (15 bits)
		RRRRRRRRRRR RR00	Long White Runlength (15 bits)

Since the compression is a bitstream, the encodings are read right (least significant bit) to left (most significant bit). The run lengths given as RRRRR in Table 153 are read in the same way (least significant bit at the right to most significant bit at the left).

There is an additional enhancement to the G4 fax algorithm, it relates to pass through mode. It is possible for data to compress negatively using the G4 fax algorithm. On occasions like this it would be easier to pass the data to the LBD as un-compressed data. Pass through mode is a new feature that was not implemented in the PEC1 version of the LBD. When the LBD is in pass through mode the least significant bit of the data stream is an un-compressed bit. This bit is used to construct the current line.

To enter pass through mode the LBD takes advantage of the way run lengths can be written. Usually if one of the runlength pair is less than or equal to 31 it should be encoded as a short runlength. However under the coding scheme of Table it is still legal to write it as a medium or long runlength. The LBD has been designed so that if a short runlength value is detected in a medium runlength then once the horizontal command containing this runlength is decoded completely this will tell the LBD to enter pass through mode and the bits following the runlength is un-compressed data. The number of bits to pass through is either a programmed number of bits or the end of the line which ever comes first. Once the pass through mode is completed the current color is the same as the color of the last bit of the passed through data.

24.2.2 DRAM Access Requirements

5

10

15

20

25

The compressed page store for contone, bi-level and raw tag data is 2 Mbytes. The LBD will access the compressed page store in single 256-bit DRAM reads. The LBD will need a 256-bit double buffer in its interface to the DIU. The LBD's DIU bandwidth requirements are summarized in Table 154

Table 154. DRAM bandwidth requirements

Direction	Maximum number of	Peak Bandwidth	Average Bandwidth
	cycles between each	(bits/cycle)	(bits/cycle)
	256-bit DRAM access		
Read	2561 (1:1 compression)	1 (1:1 compression)	0.1 (10:1
1			compression)

1: At 1:1 compression the LBD requires 1 bit/cycle or 256 bits every 256 cycles.

5 24.3 IMPLEMENTATION

24.3.1 Definitions of IO

Table 155. LBD Port List

Port Name	Pins	1/0	Description
Clocks and Resets		I	
Pclk	1	In	SoPEC Functional clock.
prst_n	1	ln	Global reset signal.
Bandstore signals			
cdu_endofbandstore[21:5]	17	ln	Address of the end of the current band of data. 256-bit word aligned DRAM address.
cdu_startofbandstore[21:5]	17	In	Address of the start of the current band of data. 256-bit word aligned DRAM address.
lbd_finishedband	1	Out	LBD finished band signal to PCU and Interrupt Controller.
DIU Interface signals			•
lbd_diu_rreq	1	Out	LBD requests DRAM read. A read request must be accompanied by a valid read address.
lbd_diu_radr[21:5]	17	Out	Read address to DIU 17 bits wide (256-bit aligned word).
diu_lbd_rack	1	In	Acknowledge from DIU that read request has been accepted and new read address can be placed on <i>lbd_diu_radr</i> .
diu_data[63:0]	64	In	Data from DIU to SoPEC Units. First 64-bits is bits 63:0 of 256 bit word. Second 64-bits is bits 127:64 of 256 bit word.

	T^{-}		Third 64-bits is bits 191:128 of 256 bit
			word.
			Fourth 64-bits is bits 255:192 of 256 bit
			word.
diu_lbd_rvalid	1	ln	Signal from DIU telling SoPEC Unit that
			valid read data is on the diu_data bus
PCU Interface data and co	ontrol sign	als	
pcu_addr[5:2]	4	ln	PCU address bus. Only 4 bits are
			required to decode the address space
			for this block.
pcu_dataout[31:0]	32	In	Shared write data bus from the PCU.
lbd_pcu_datain[31:0]	32	Out	Read data bus from the LBD to the PCU.
pcu_rwn	1	ln	Common read/not-write signal from the PCU.
pcu_lbd_sel	1	ln	Block select from the PCU. When
			pcu_lbd_sel is high both pcu_addr and
			pcu_dataout are valid.
lbd_pcu_rdy	1	Out	Ready signal to the PCU. When
			/bd_pcu_rdy is high it indicates the last
			cycle of the access. For a write cycle this
			means pcu_dataout has been registered
			by the block and for a read cycle this
			means the data on Ibd_pcu_datain is
			valid.
SFU Interface data and co	ontrol sign	als	
sfu_lbd_rdy	1	ln	Ready signal indicating SFU has
			previous line data
			available for reading and is also ready to
			be written
			to.
lbd_sfu_advline	1	Out	Advance line signal to previous and next
			line buffers
lbd_sfu_pladvword	1	Out	Advance word signal for previous line buffer.
sfu_lbd_pldata[15:0]	16	ln	Data from the previous line buffer.
lbd_sfu_wdata[15:0]	16	Out	Write data for next line buffer.
lbd_sfu_wdatavalid	1	Out	Write data valid signal for next line buffer

24.3.2 Configuration Registers

24.3.3 Starting the LBD between bands

20

The LBD should be started *after* the SFU. The LBD is programed with a start address for the compressed bi-level data, a decode line length, the source of the previous line and a count of how many lines to decode. The LBD's *NextBandEnable* bit should then be set (this will set LBD *Go*).

The LBD decodes a single band and then stops, clearing it's *Go* bit and issuing a pulse on *lbd_finishedband*. The LBD can then be restarted for the next band, while the HCU continues to process previously decoded bi-level data from the SFU.

There are 4 mechanisms for restarting the LBD between bands:

- a. Ibd_finishedband causes an interrupt to the CPU. The LBD will have stopped and cleared its Go bit. The CPU reprograms the LBD, typically the NextBandCurrReadAdr, NextBandLines-Remaining and NextBandPrevLineSource shadow registers, and sets NextBandEnable to restart the LBD.
- b. The CPU programs the LBD's NextBandCurrReadAdr, NextBandLinesRemaining, and Next-BandPrevLineSource shadow registers and sets the NextBandEnable flag before the end of the current band. At the end of the band the LBD clears Go, NextBandEnable is already set so the LBD restarts immediately.
 - c. The PCU is programmed so that Ibd_finishedband triggers the PCU to execute commands from DRAM to reprogram the LBD's NextBandCurrReadAdr, NextBandLinesRemaining, and NextBandPrevLineSource shadow registers and set NextBandEnable to restart the LBD. The advantage of this scheme is that the CPU could process band headers in advance and store the band commands in DRAM ready for execution.

d. This is a combination of *b* and *c* above. The PCU (rather than the CPU in *b*) programs the LBD's *NextBandCurrReadAdr*, *NextBandLinesRemaining*, and *NextBandPrevLineSource* shadow registers and sets the *NextBandEnable* flag before the end of the current band. At the end of the band the LBD clears *Go* and pulses *lbd_finishedband*. *NextBandEnable* is already set so the LBD restarts immediately. Simultaneously, *lbd_finishedband* triggers the PCU to fetch commands from DRAM. The LBD will have restarted by the time the PCU has fetched commands from DRAM. The PCU commands program the LBD's shadow registers and sets *NextBandEnable* for the next band.

24.3.4 Top-level Description

5

10 A block diagram of the LBD is shown in Figure 148.

The LBD contains the following sub-blocks:

Table 157. Functional sub-blocks in the LBD

name	Description
Registers and Resets	PCU interface and configuration registers. Also generates the Go and
	the <i>Reset</i> signals for the rest of the LBD
Stream Decoder	Accesses the bi-level description from the DRAM through the DIU inter-
	face. It decodes the bit stream into a command with arguments, which it
	then passes to the command controller.
Command Controller	Interprets the command from the stream decoder and provide the line fill
	unit with a limit address and color to fill the SFU Next Line Buffer. It also
	provides the next edge unit starting address to look for the next edge.
Next Edge Unit	Scans through the Previous Line Buffer using its current address to find
	the next edge of a color provided by the command controller. The next
	edge unit outputs this as the next current address back to the command
	controller and sets a valid bit when this address is at the next edge.
Line Fill Unit	Fills the SFU Next Line Buffer with a color from its current address up to
	a limit address. The color and limit are provided by the command
	controller.

In the following description the LBD decodes data for its current decode line but writes this data into the SFU's *next* line buffer.

Naming of signals and logical blocks are taken from [22].

The LBD is able to stall mid-line should the SFU be unable to supply a previous line or receive a current line frame due to band processing latency.

- All output control signals from the LBD must always be valid after reset. For example, if the LBD is not currently decoding, *lbd_sfu_advline* (to the SFU) and *lbd_finishedband* will always be 0.
 - 24.3.5 Registers and Resets sub-block description

Since the CDU, LBD and TE all access the page band store, they share two registers that enable sequential memory accesses to the page band stores to be circular in nature. The CDU chapter lists these two registers. The register descriptions for the LBD are listed in Table

During initialisation of the LBD, the *LineLength* and the *LinesRemaining* configuration values are written to the LBD. The 'Registers and Resets' sub-block supplies these signals to the other sub-blocks in the LBD. In the case of *LinesRemaining*, this number is decremented for every line that is completed by the LBD.

If pass through is used during a band the *PassThroughEnable* register needs to be programmed and *PassThroughDotLength* programmed with the length of the compressed bits in pass through mode.

PrevLineSource is programmed during the initialisation of a band, if the previous line supplied for the first line is a valid previous line, a 1 is written to PrevLineSource so that the data is used. If a 0 is written the LBD ignores the previous line information supplied and acts as if it is receiving all zeros for the previous line regardless of what the out of the SFU is.

The 'Registers and Resets' sub-block also generates the resets used by the rest of the LBD and the Go bit which tells the LBD that it can start requesting data from the DIU and commence decoding of the compressed data stream.

24.3.6 Stream Decoder Sub-block Description

The Stream Decoder reads the compressed bi-level image from the DRAM via the DIU (single accesses of 256-bits) into a double 256-bit FIFO. The barrel shift register uses the 64-bit word from the FIFO to fill up the empty space created by the barrel shift register as it is shifting it's contents. The bit stream is decoded into a command/arguments pair, which in turn is passed to the command controller.

A dataflow block diagram of the stream decoder is shown in Figure 149.

25 24.3.6.1 DecodeC - Decode Command

5

10

20

30

35

The *DecodeC* logic encodes the command from bits 6..0 of the bit stream to output one of three commands: *SKIP*, *VERTICAL* and *RUNLENGTH*. It also provides an output to indicate how many bits were consumed, which feeds back to the barrel shift register.

There is a fourth command, *PASS_THROUGH*, which is not encoded in bits 6..0, instead it is inferred in a special runlength. If the stream decoder detects a short runlength value, i.e. a number less than 31, encoded as a medium runlength this tell the Stream Decoder that once the horizontal command containing this runlength is decoded completely the LBD enters *PASS_THROUGH* mode. Following the runlength there will be a number of bits that represent uncompressed data. The LBD will stay in *PASS_THROUGH* mode until all these bits have been decoded successfully, this will occur once a programmed number of bits is reached or the line ends, which ever comes first.

24.3.6.2 DecodeD - Decode Delta

The *DecodeD* logic decodes the run length from bits 20..3 of the bit stream. If *DecodeC* is decoding a vertical command, it will cause *DecodeD* to put constants of -3 through 3 on its output.

The output delta is a 15 bit number, which is generally considered to be positive, but since it

needs to only address to 13824 dots for an A4 page and 19488 dots for an A3 page (of 32,768), a 2's complement representation of -3,-2,-1 will work correctly for the data pipeline that follows. This unit also outputs how many bits were consumed.

In the case of *PASS_THROUGH* mode, *DecodeD* parses the bits that represent the uncompressed data and this is used by the Line Fill Unit to construct the current line frame.

DecodeD parses the bits at one bit per clock cycle and passes the bit in the less significant bit location of delta to the line fill unit.

DecodeD currently requires to know the color of the run length to decode it correctly as black and white runs are encoded differently. The stream decoder keeps track of the next color based on the current color and the current command.

24.3.6.3 State-machine

5

10

15

20

25

This state machine continuously fetches consecutive DRAM data whenever there is enough free space in the FIFO, thereby keeping the barrel shift register full so it can continually decode commands for the command controller. Note in Figure 149 that each read cycle *curr_read_addr* is compared to *end_of_band_store*. If the two are equal, *curr_read_addr* is loaded with *start_of_band_store* (circular memory addressing). Otherwise *curr_read_addr* is simply incremented. *start_of_band_store* and *end_of_band_store* need to be programed so that the

When the state machine decodes a *SKIP* command, the state machine provides two *SKIP* instructions to the command controller.

distance between them is a multiple of the 256-bit DRAM word size.

The RUNLENGTH command has two different run lengths. The two run lengths are passed to the command controller as separate RUNLENGTH instructions. In the first instruction fetch, the first run length is passed, and the state machine selects the DecodeD shift value for the barrel shift. In the second instruction fetch from the command controller another RUNLENGTH instruction is generated and the respective shift value is decoded. This is achieved by forcing DecodeC to output a second RUNLENGTH instruction and the respective shift value is decoded.

For PASS_THROUGH mode, the PASS_THROUGH command is issued every time the command controller requests a new command. It does this until all the un-compressed bits have

30 24.3.7 Command Controller Sub-block Description

The Command Controller interprets the command from the Stream Decoder and provides the line fill unit with a limit address and color to fill the SFU Next Line Buffer. It provides the next edge unit with a starting address to look for the next edge and is responsible for detecting the end of line and generating the *eob_cc* signal that is passed to the line fill unit.

A dataflow block diagram of the command controller is shown in Figure 150. Note that data names such as *a0* and *b1p* are taken from [22], and they denote the reference or starting changing element on the coding line and the first changing element on the reference line to the right of *a0* and of the opposite color to *a0* respectively.

24.3.7.1 State machine

been processed.

The following is an explanation of all the states that the state machine utilizes.

i START

This is the state that the Command Controller enters when a hard or soft reset occurs or when *Go* has been de-asserted. This state cannot be left until the reset has been removed, *Go* has been asserted and the *NEU* (Next Edge Unit), the *SD* (Stream Decoder) and the SFU are ready.

5 ii AWAIT_BUFFER

The *NEU* contains a buffer memory for the data it receives from the SFU. When the command controller enters this state the *NEU* detects this and starts buffering data, the command controller is able to leave this state when the state machine in the *NEU* has entered the *NEU_RUNNING* state. Once this occurs the command controller can proceed to the *PARSE* state.

10 iii PAUSE_CC

During the decode of a line it is possible for the FIFO in the stream decoder to get starved of data if the DRAM is not able to supply replacement data fast enough. Additionally the SFU can also stall mid-line due to band processing latency. If either of these cases occurs the LBD needs to pause until the stream decoder gets more of the compressed data stream from the DRAM or the SFU can receive or deliver new frames. All of the remaining states check if *sdvalid* goes to zero (this denotes a starving of the stream decoder) or if *sfu_lbd_rdy* goes to zero and that the LBD needs to pause. *PAUSE_CC* is the state that the command controller enters to achieve this and it does not leave this state until *sdvalid* and *sfu_lbd_rdy* are both asserted and the LBD can recommence decompressing.

20 iv PARSE

15

30

35

40

Once the command controller enters the PARSE state it uses the information that is supplied by the stream decoder. The first clock cycle of the state sees the *sdack* signal getting asserted informing the stream decoder that the current register information is being used so that it can fetch the next command.

- When in this state the command controller can receive one of four valid commands:
 - a) Runlength or Horizontal

For this command the value given as delta is an integer that denotes the number of bits of the current color that must be added to the current line.

Should the current line position, *a0*, be added to the delta and the result be greater than the final position of the current frame being processed by the Line Fill Unit (only 16 bits at a time), it is necessary for the command controller to wait for the Line Fill Unit (LFU) to process up to that point. The command controller changes into the *WAIT_FOR_RUNLENGTH* state while this occurs.

When the current line position, *a0*, and the delta together equal or exceed the LINE_LENGTH, which is programmed during initialisation, then this denotes that it is the end of the current line. The command controller signals this to the rest of the LBD and then returns to the *START* state. *b)* Vertical

When this command is received, it tells the command controller that, in the previous line, it needs to find a change from the current color to opposite of the current color, i.e. if the current color is white it looks from the current position in the previous line for the next time where there is a

change in color from white to black. It is important to note that if a black to white change occurs first it is ignored.

Once this edge has been detected, the delta will denote which of the vertical commands to use, refer to Table . The delta will denote where the changing element in the current line is relative to the changing element on the previous line, for a Vertical(2) the new changing element position in the current line will correspond to the two bits extra from changing element position in the previous line.

Should the next edge not be detected in the current frame under review in the *NEU*, then the command controller enters the *WAIT_FOR_NE* state and waits there until the next edge is found.

10 c) Skip

5

20

30

40

A skip follow the same functionality as to *Vertical*(0) commands but the color in the current line is not changed as it is been filled out. The stream decoder supplies what looks like two separate skip commands that the command controller treats the same a two *Vertical*(0) commands and has been coded not to change the current color in this case.

15 d) Pass Through

When in pass through mode the stream decoder supplies one bit per clock cycle that is uses to construct the current frame. Once pass through mode is completed, which is controlled in the stream decoder, the LBD can recommence normal decompression again. The current color after pass through mode is the same color as the last bit in un-compressed data stream. Pass through mode does not need an extra state in the command controller as each pass through command received from the stream decoder can always be processed in one clock cycle.

v WAIT_FOR_RUNLENGTH

As some RUNLENGTH's can carry over more than one 16-bit frame, this means that the Line Fill Unit needs longer than one clock cycle to write out all the bits represented by the RUNLENGTH.

After the first clock cycle the command controller enters into the WAIT_FOR_RUNLENGTH state until all the RUNLENGTH data has been consumed. Once finished and provided it is not the end of the line the command controller will return to the PARSE state.

vi WAIT_FOR_NE

Similar to the RUNLENGTH commands the vertical commands can sometimes not find an edge in the current 16-bit frame. After the first clock cycle the command controller enters the WAIT_FOR_NE state and remains here until the edge is detected. Provided it is not the end of the line the command controller will return to the PARSE state.

vii FINISH_LINE

At the end of a line the command controller needs to hold its data for the SFU before going back to the START state. Command controller remains in the *FINISH_LINE* state for one clock cycle to achieve this.

24.3.8 Next Edge Unit Sub-block Description

The Next Edge Unit (NEU) is responsible for detecting color changes, or edges, in the previous line based on the current address and color supplied by the Command Controller. The NEU is the interface to the SFU and it buffers the previous line for detecting an edge. For an edge detect

operation the Command Controller supplies the current address, this typically was the location of the last edge, but it could also be the end of a run length. With the current address a color is also supplied and using these two values the *NEU* will search the previous line for the next edge. If an edge is found the *NEU* returns this location to the Command Controller as the next address in the current line and it sets a valid bit to tell the Command Controller that the edge has been detected. The Line Fill Unit uses this result to construct the current line. The *NEU* operates on 16-bit words and it is possible that there is no edge in the current 16 bits in the *NEU*. In this case the NEU will request more words from the SFU and will keep searching for an edge. It will continue doing this until it finds an edge or reaches the end of the previous line, which is based on the

10 LINE_LENGTH. A dataflow block diagram of the Next Edge unit is shown in Figure 152. 24.3.8.1 NEU Buffer

5

15

20

25

30

35

The algorithm being employed for decompression is based on the whole previous line and is not delineated during the line. However the *Next Edge Unit*, *NEU*, can only receive 16 bits at a time from the SFU. This presents a problem for vertical commands if the edge occurs in the successive frame, but refers to a changing element in the current frame.

To accommodate this the *NEU* works on two frames at the same time, the current frame and the first 3 bits from the successive frame. This allows for the information that is needed from the previous line to construct the current frame of the current line.

In addition to this buffering there is also buffering right after the data is received from the SFU as the SFU output is not registered. The current implementation of the SFU takes two clock cycles from when a request for a current line is received until it is returned and registered. However when NEU requests a new frame it needs it on the next clock cycle to maintain a decoded rate of 2 bits per clock cycle. A more detailed diagram of the buffer in the NEU is shown in Figure 153. The output of the buffer are two 16-bit vectors, use_prev_line_a and use_prev_line_b, that are used to detect an edge that is relevant to the current line being put together in the Line Fill Unit. 24.3.8.2 NEU Edge Detect

The *NEU* Edge Detect block takes the two 16 bit vectors supplied by the buffer and based on the current line position in the current line, *a0*, and the current color, *sd_color*, it will detect if there is an edge relevant to the current frame. If the edge is found it supplies the current line position, *b1p*, to the command controller and the line fill unit. The configuration of the edge detect is shown in Figure 154.

The two vectors from the buffer, use_prev_line_a and use_prev_line_b, pass into two sub-blocks, transition_wtob and transition_btow. transition_wtob detects if any white to black transitions occur in the 19 bit vector supplied and outputs a 19-bit vector displaying the transitions. transition_wtob is functionally the same as transition_btow, but it detects white to black transitions.

The two 19-bit vectors produced enter into a multiplexer and the output of the multiplexer is controlled by color_neu. color_neu is the current edge transition color that the edge detect is searching for.

The output of the multiplexer is masked against a 19-bit vector, the mask is comprised of three parts concatenated together: decode_b_ext, decode_b and FIRST_FLU_WRITE.

The output of *transition_wtob* (and it complement *transition_btow*) are all the transitions in the 16 bit word that is under review. The *decode_b* is a mask generated from *a0*. In bit-wise terms all the bits above and including *a0* are 1's and all bits below *a0* are 0's. When they are gated together it means that all the transitions below *a0* are ignored and the first transition after *a0* is picked out as the next edge.

The *decode_b* block decodes the 4 lsb of the current address (*a0*) into 16-bit mask bits that control which of the data bits are examined. Table 158 shows the truth table for this block.

Table 158. Decode_b truth table

For cases when there is a negative vertical command from the stream decoder it is possible that the edge is in the three lower significant bits of the next frame. The *decode_b_ext* block supplies the mask so that the necessary bits can be used by the *NEU* to detect an edge if present, Table 159 shows the truth table for this block.

FIRST_FLU_WRITE is only used in the first frame of the current line. 2.2.5 a) in [22] refers to "Processing the first picture element", in which it states that "The first starting picture element, a0, on each coding line is imaginarily set at a position just before the first picture element, and is regarded as a white picture element". transition_wtob and transition_btow are set up produce this case for every single frame. However it is only used by the NEU if it is not masked out. This occurs when FIRST_FLU_WRITE is '1' which is only asserted at the beginning of a line.

2.2.5 b) in [22] covers the case of "Processing the last picture element", this case states that "The coding of the coding line continues until the position of the imaginary changing element situated after the last actual element is coded". This means that no matter what the current color is the NEU needs to always find an edge at the end of a line. This feature is used with negative vertical commands.

The vector, <code>end_frame</code>, is a "one-hot" vector that is asserted during the last frame. It asserts a bit in the end of line position, as determined by <code>LineLength</code>, and this simulates an edge in this location which is ORed with the transition's vector. The output of this, <code>masked_data</code>, is sent into the <code>encodeB_one_hot</code> block

24.3.8.3 Encode_b_one_hot

5

10

15

20

The *encode_b_one_hot* block is the first stage of a two stage process that encodes the data to determine the address of the 0 to 1 transition. Table 160 lists the truth table outlining the functionally required by this block.

Table 160. Encode_b_one_hot Truth Table

The output of encode_b_one_hot is a "one-hot" vector that will denote where that edge transition is located. In cases of multiple edges, only the first one will be picked.

24.3.8.4 Encode_b_4bit

5 Encode_b_4bit is the second stage of the two stage process that encodes the data to determine the address of the 0 to 1 transition.

Encode_b_4bit receives the "one-hot" vector from encode_b_one_hot and determines the bit location that is asserted. If there is none present this means that there was no edge present in this frame. If there is a bit asserted the bit location in the vector is converted to a number, for example if bit 0 is asserted then the number is one, if bit one is asserted then the number is one, etc. The delta supplied to the NEU determines what vertical command is being processed. The formula that is implemented to return b1p to the command controller is:

for V(n) blp = x + n modulus16

where x is the number that was extracted from the "one-hot" vector and n is the vertical command.

24.3.8.5 State machine

The following is an explanation of all the states that the NEU state machine utilizes.

20 i NEU_START

10

15

35

This is the state that NEU enters when a hard or soft reset occurs or when *Go* has been deasserted. This state can not left until the reset has been removed, *Go* has been asserted and it detects that the command controller has entered it's *AWAIT_BUFF* state. When this occurs the *NEU* enters the *NEU_FILL_BUFF* state.

25 ii NEU_FILL_BUFF

Before any compressed data can be decoded the *NEU* needs to fill up its buffer with new data from the SFU. The rest of the LBD waits while the *NEU* retrieves the first four frames from the previous line. Once completed it enters the *NEU_HOLD* state.

iii NEU_HOLD

The NEU waits in this state for one clock cycle while data requested from the SFU on the last access returns.

iv NEU_RUNNING

NEU_RUNNING controls the requesting of data from the SFU for the remainder of the line by pulsing *lbd_sfu_pladvword* when the LBD needs a new frame from the SFU. When the *NEU* has received all the word it needs for the current line, as denoted by the *LineLength*, the NEU enters the *NEU_EMPTY* state.

v NEU_EMPTY

NEU waits in this state while the rest of the LBD finishes outputting the completed line to the SFU. The NEU leaves this state when *Go* gets deasserted. This occurs when the *end_of_line* signal is detected from the LBD.

5 24.3.9 Line Fill Unit sub-block description

The Line Fill Unit, LFU, is responsible for filling the next line buffer in the SFU. The SFU receives the data in blocks of sixteen bits. The LFU uses the color and *a0* provided by the Command Controller and when it has put together a complete 16-bit frame, it is written out to the SFU. The LBD signals to the SFU that the data is valid by strobing the *lbd_sfu_wdatavalid* signal.

When the LFU is at the end of the line for the current line data it strobes *lbd_sfu_advline* to indicate to the SFU that the end of the line has occurred.

A dataflow block diagram of the line fill unit is shown in Figure 154.

The dataflow above has the following blocks:

24.3.9.1 State Machine

15 The following is an explanation of all the states that the LFU state machine utilizes.

i LFU_START

This is the state that the LFU enters when a hard or soft reset occurs or when *Go* has been deasserted. This state can not left until the reset has been removed, *Go* has been asserted and it detects that *a0* is no longer zero, this only occurs once the command controller start processing data from the *Next Edge Unit*, *NEU*.

ii LFU NEW REG

20

25

30

35

LFU_NEW_REG is only entered at the beginning of a new frame. It can remain in this state on subsequent cycles if a whole frame is completed in one clock cycle. If the frame is completed the LFU will output the data to the SFU with the write enable signal. However if a frame is not completed in one clock cycle the state machine will change to the LFU_COMPLETE_REG state to complete the remainder of the frame. LFU_NEW_REG handles all the lbd_sfu_wdata writes and asserts lbd_sfu_wdatavalid as necessary.

iii LFU_COMPLETE_REG

LFU_COMPLETE_REG fills out all the remaining parts of the frame that were not completed in the first clock cycle. The command controller supplies the a0 value and the color and the state machine uses these to derive the *limit* and *color_sel_16bit_lf* which the *line_fill_data* block needs to construct a frame. Limit is the four lower significant bits of a0 and color_sel_16bit_lf is a 16-bit wide mask of sd_color. The state machine also maintains a check on the upper eleven bits of a0. If these increment from one clock cycle to the next that means that a frame is completed and the data can be written to the SFU. In the case of the LineLength being reached the Line Fill Unit fills out the remaining part of the frame with the color of the last bit in the line that was decoded.

24.3.9.2 line_fill_data

line_fill_data takes the *limit* value and the *color_sel_16bit_lf* values and constructs the current frame that the command controller and the next edge unit are decoding. The following pseudo

code illustrate the logic followed by the line_fill_data. work_sfu_wdata is exported by the LBD to the SFU as lbd_sfu_wdata.

- 25 Spot FIFO Unit (SFU)
- 25.1 OVERVIEW

The Spot FIFO Unit (SFU) provides the means by which data is transferred between the LBD and the HCU. By abstracting the buffering mechanism and controls from both units, the interface is clean between the data user and the data generator. The amount of buffering can also be increased or decreased without affecting either the LBD or HCU. Scaling of data is performed in the horizontal and vertical directions by the SFU so that the output to the HCU matches the printer resolution. Non-integer scaling is supported in both the horizontal and vertical directions.

Typically, the scale factor will be the same in both directions but may be programmed to be different.

25.2 MAIN FEATURES OF THE SFU

The SFU replaces the Spot Line Buffer Interface (SLBI) in PEC1. The spot line store is now located in DRAM.

The SFU outputs the previous line to the LBD, stores the next line produced by the LBD and outputs the HCU read line. Each interface to DRAM is via a feeder FIFO. The LBD interfaces to the SFU with a data width of 16 bits. The SFU interfaces to the HCU with a data width of 1 bit. Since the DRAM word width is 256-bits but the LBD line length is a multiple of 16 bits, a capability to flush the last multiples of 16-bits at the end of a line into a 256-bit DRAM word size is required. Therefore, SFU reads of DRAM words at the end of a line, which do not fill the DRAM word, will already be padded.

A signal *sfu_lbd_rdy* to the LBD indicates that the SFU is available for writing and reading. For the first LBD line after SFU *Go* has been asserted, previous line data is not supplied until after the first *lbd_sfu_advline* strobe from the LBD (zero data is supplied instead), and *sfu_lbd_rdy* to the LBD indicates that the SFU is available for writing. *lbd_sfu_advline* tells the SFU to advance to the next line. *lbd_sfu_pladvword* tells the SFU to supply the next 16-bits of previous line data. Until the number of *lbd_sfu_pladvword* strobes received is equivalent to the LBD line length, *sfu_lbd_rdy* indicates that the SFU is available for both reading and writing. Thereafter it indicates the SFU is available for writing. The LBD should not generate *lbd_sfu_pladvword* or *lbd_sfu_advline* strobes until *sfu_lbd_rdy* is asserted.

A signal *sfu_hcu_avail* indicates that the SFU has data to supply to the HCU. Another signal *hcu_sfu_advdot*, from the HCU, tells the SFU to supply the next dot. The HCU should not

generate the *hcu_sfu_advdot* signal until *sfu_hcu_avail* is true. The HCU can therefore stall waiting for the *sfu_hcu_avail* signal.

X and Y non-integer scaling of the bi-level dot data is performed in the SFU.

At 1600 dpi the SFU requires 1 dot per cycle for all DRAM channels, 3 dots per cycle in total (read + read + write). Therefore the SFU requires two 256 bit read DRAM access per 256 cycles, 1 write access every 256 cycles. A single DIU read interface will be shared for reading the current and previous lines from DRAM.

25.3 BI-LEVEL DRAM MEMORY BUFFER BETWEEN LBD, SFU AND HCU

Figure 158 shows a bi-level buffer store in DRAM. Figure 158 (a) shows the LBD previous line address reading after the HCU read line address in DRAM. Figure 158 (b) shows the LBD previous line address reading before the HCU read line address in DRAM.

Although the LBD and HCU read and write complete lines of data, the bi-level DRAM buffer is not line based. The buffering between the LBD, SFU and HCU is a FIFO of programmable size. The only line based concept is that the line the HCU is currently reading cannot be over-written

because it may need to be re-read for scaling purposes.

The SFU interfaces to DRAM via three FIFOs:

5

30

35

40

- a. The HCUReadLineFIFO which supplies dot data to the HCU.
- b. The LBDNextLineFIFO which writes decompressed bi-level data from the LBD.
- c. The LBDPrevLineFIFO which reads previous decompressed bi-level data for the LBD.
- There are four address pointers used to manage the bi-level DRAM buffer:
 - a. hcu_readline_rd_adr[21:5] is the read address in DRAM for the HCUReadLineFIFO.
 - b. hcu_startreadline_adr[21:5] is the start address in DRAM for the current line being read by the HCUReadLineFIFO.
 - c. Ibd_nextline_wr_adr[21:5] is the write address in DRAM for the LBDNextLineFIFO.
- 25 d. <code>lbd_prevline_rd_adr[21:5]</code> is the read address in DRAM for the <code>LBDPrevLineFIFO</code>.

The address pointers must obey certain rules which indicate whether they are valid:

- a. hcu_readline_rd_adr is only valid if it is reading earlier in the line than lbd_nextline_wr_adr is writing i.e. the fifo is not empty
- b. The SFU (*lbd_nextline_wr_adr*) cannot overwrite the current line that the HCU is reading from (*hcu_startreadline_adr*) i.e. the fifo is not full, when compared with the HCU read line pointer
- c. The LBDNextLineFIFO (Ibd_nextline_wr_adr) must be writing earlier in the line than LBD-PrevLineFIFO (Ibd_prevline_rd_adr) is reading and must not overwrite the current line that the HCU is reading from i.e. the fifo is not full when compared to the PrevLineFifo read pointer
- d. The LBDPrevLineFIFO (Ibd_prevline_rd_adr) can read right up to the address that LBDNext-LineFIFO (Ibd_nextline_wr_adr) is writing i.e the fifo is not empty.
 - e. At startup i.e. when sfu_go is asserted, the pointers are reset to start_sfu_adr[21:5].
- f. The address pointers can wrap around the SFU bi-level store area in DRAM.

As a guideline, the typical FIFO size should be a minimum of 2 lines stored in DRAM, nominally 3 lines, up to a programmable number of lines. A larger buffer allows lines to be decompressed in advance. This can be useful for absorbing local complexities in compressed bi-level images.

25.4 DRAM ACCESS REQUIREMENTS

The SFU has 1 read interface to the DIU and 1 write interface. The read interface is shared between the previous and current line read FIFOs.

The spot line store requires 5.1 Kbytes of DRAM to store 3 A4 lines. The SFU will read and write the spot line store in single 256-bit DRAM accesses. The SFU will need 256-bit double buffers for each of its previous, current and next line interfaces.

The SFU's DIU bandwidth requirements are summarized in Table 161.

Table 161. DRAM bandwidth requirements

Write	2562	1	1
Read	1281	2	2
	256-bit DRAM access	(bits/cycle)	(bits/cycle)
	cycles between each	to be supported by DIU	Bandwidth
Direction	Maximum number of	Peak Bandwidth required	Average

- 10 1: Two separate reads of 1 bit/cycle.
 - 2: Write at 1 bit/cycle.

25.5 SCALING

5

15

30

Scaling of bi-level data is performed in both the horizontal and vertical directions by the SFU so that the output to the HCU matches the printer resolution. The SFU supports non-integer scaling with the scale factor represented by a numerator and a denominator. Only scaling up of the bi-level data is allowed, i.e. the numerator should be greater than or equal to the denominator. Scaling is implemented using a counter as described in the pseudocode below. An advance pulse is generated to move to the next dot (x-scaling) or line (y-scaling).

X scaling controls whether the SFU supplies the next dot or a copy of the current dot when the HCU asserts hcu_sfu_advdot . The SFU counts the number of hcu_sfu_advdot signals from the HCU. When the SFU has supplied an entire HCU line of data, the SFU will either re-read the current line from DRAM or advance to the next line of HCU read data depending on the programmed Y scale factor.

An example of scaling for *numerator* = 7 and *denominator* = 3 is given in Table 162. The signal *advance* if asserted causes the next input dot to be output on the next cycle, otherwise the same input dot is output

Table 162. Non-integer scaling example for scaleNum = 7, scaleDenom = 3

count	advance	dot
0	0	1
3	0	1
6	1	1
3 6 2 5	0	2
5	1	2
1	0	3
4	1	3
0 3 6 2	0	4
3	0	4
6	1	4
2	0	5

25.6 LEAD-IN AND LEAD-OUT CLIPPING

To account for the case where there may be two SoPEC devices, each generating its own portion of a dot-line, the first dot in a line may not be replicated the total scale-factor number of times by an individual SoPEC. The dot will ultimately be scaled-up correctly with both devices doing part of the scaling, one on its lead-out and the other on its lead in. Scaled up dots on the lead-out, i.e. which go beyond the HCU linelength, will be ignored. Scaling on the lead-in, i.e. of the first valid dot in the line, is controlled by setting the *XstartCount* register.

At the start of each line *count* in the pseudo-code above is set to *XstartCount*. If there is no leadin, *XstartCount* is set to 0 i.e. the first value of *count* in Table . If there is lead-in then *XstartCount* needs to be set to the appropriate value of *count* in the sequence above.

25.7 INTERFACES BETWEEN LDB, SFU AND HCU

25.7.1 LDB-SFU Interfaces

5

10

The LBD has two interfaces to the SFU. The LBD writes the next line to the SFU and reads the previous line from the SFU.

15 25.7.1.1 LBDNextLineFIFO Interface

The LBDNextLineFIFO interface from the LBD to the SFU comprises the following signals:

- Ibd_sfu_wdata, 16-bit write data.
- Ibd_sfu_wdatavalid, write data valid.
- Ibd_sfu_advline, signal indicating LDB has advanced to the next line.
- The LBD should not write to the SFU until *sfu_lbd_rdy* is true. The LBD can therefore stall waiting for the *sfu_lbd_rdy* signal.

25.7.1.2 LBDPrevLineFIFO Interface

The LBDPrevLineFIFO interface from the SFU to the LBD comprises the following signals:

- sfu_lbd_pldata, 16-bit data.
- The previous line read buffer interface from the LBD to the SDU comprises the following signals:
 - lbd_sfu_pladvword, signal indicating to the SFU to supply the next 16-bit word.
 - Ibd_sfu_advline, signal indicating LDB has advanced to the next line.

Previous line data is not supplied until after the first *lbd_sfu_advline* strobe from the LBD (zero data is supplied instead). The LBD should not assert *lbd_sfu_pladvword* unless *sfu_lbd_rdy* is asserted.

25.7.1.3 Common Control Signals

5 sfu_lbd_rdy indicates to the LBD that the SFU is available for writing. After the first lbd_sfu_advline and before the number of lbd_sfu_pladvword strobes received is equivalent to the LBD line length, sfu_lbd_rdy indicates that the SFU is available for both reading and writing. Thereafter it indicates the SFU is available for writing.

The LBD should not generate *lbd_sfu_pladvword* or *lbd_sfu_advline* strobes until *sfu_lbd_rdy* is asserted.

25.7.2 SFU-HCU Current Line FIFO Interface

The interface from the SFU to the HCU comprises the following signals:

- sfu_hcu_sdata, 1-bit data.
- sfu_hcu_avail, data valid signal indicating that there is data available in the SFU HCUReadLineFIFO.

The interface from HCU to SFU comprises the following signals:

• hcu_sfu_advdot, indicating to the SFU to supply the next dot.

The HCU should not generate the *hcu_sfu_advdot* signal until *sfu_hcu_avail* is true. The HCU can therefore stall waiting for the *sfu_hcu_avail* signal.

25.8.1 Definitions of IO

Table 163. SFU Port List

Port Name	Pins	1/0	Description
Clocks and Resets	<u> </u>	<u>t</u>	
Pclk	1	ln	SoPEC Functional clock.
prst_n	1	ln	Global reset signal.
DIU Read Interface signals			
sfu_diu_rreq	1	Out	SFU requests DRAM read. A read request must
			be accompanied by a valid read address.
sfu_diu_radr[21:5]	17	Out	Read address to DIU
			17 bits wide (256-bit aligned word).
diu_sfu_rack	1	ln	Acknowledge from DIU that read request has
			been accepted and new read address can be
			placed on <i>sfu_diu_radr.</i>
diu_data[63:0]	64	In	Data from DIU to SoPEC Units.
			First 64-bits are bits 63:0 of 256 bit word.
			Second 64-bits are bits 127:64 of 256 bit word.
			Third 64-bits are bits 191:128 of 256 bit word.

			le 11 04 11 11 11 11 11 11 11 11 11 11 11 11 11
		<u> </u>	Fourth 64-bits are bits 255:192 of 256 bit word.
diu_sfu_rvalid	1	ln	Signal from DIU telling SoPEC Unit that valid
·			read data is on the <i>diu_data</i> bus.
DIU Write Interface signal	ls		
sfu_diu_wreq	1	Out	SFU requests DRAM write. A write request
			must be accompanied by a valid write address
			together with valid write data and a write valid.
sfu_diu_wadr[21:5]	17	Out	Write address to DIU
			17 bits wide (256-bit aligned word).
diu_sfu_wack	1	ln	Acknowledge from DIU that write request has
			been accepted and new write address can be
			placed on <i>sfu_diu_wadr</i> .
sfu_diu_data[63:0]	64	Out	Data from SFU to DIU.
			First 64-bits are bits 63:0 of 256 bit word.
			Second 64-bits are bits 127:64 of 256 bit word.
			Third 64-bits are bits 191:128 of 256 bit word.
			Fourth 64-bits are bits 255:192 of 256 bit word.
sfu_diu_wvalid	1	Out	Signal from PEP Unit indicating that data on
			sfu_diu_data is valid.
PCU Interface data and c	ontrol sigr	nals	
pcu_adr[5:2]	4	ln	PCU address bus. Only 4 bits are required to
			decode the address space for this block
pcu_dataout[31:0]	32	ln	Shared write data bus from the PCU
sfu_pcu_datain[31:0]	32	Out	Read data bus from the SFU to the PCU
pcu_rwn	1	ln	Common read/not-write signal from the PCU
pcu_sfu_sel	1	ln	Block select from the PCU. When pcu_sfu_sel
			is high both <i>pcu_adr</i> and <i>pcu_dataout</i> are valid
sfu_pcu_rdy	1	Out	Ready signal to the PCU. When sfu_pcu_rdy is
			high it indicates the last cycle of the access. For
			a write cycle this means pcu_dataout has been
			registered by the block and for a read cycle this
			means the data on sfu_pcu_datain is valid.
LBD Interface Data and C	ontrol Sig	nals	
sfu_lbd_rdy	1	Out	Signal indication that SFU has previous line
			data available and is ready to be written to.
lbd_sfu_advline	1	ln	Line advance signal for both next and previous
			lines.
lbd_sfu_pladvword	1	ln	Advance word signal for previous line buffer.
sfu_lbd_pldata[15:0]	16	Out	Data from the previous line buffer.
			

lbd_sfu_wdata[15:0]	16	ln	Write data for next line buffer.
lbd_sfu_wdatavalid	1	In	Write data valid signal for next line buffer data.
HCU Interface Data and	Control Si	gnals	
hcu_sfu_advdot	1	in	Signal indicating to the SFU that the HCU is ready to accept the next dot of data from SFU.
sfu_hcu_sdata	1	Out	Bi-level dot data.
sfu_hcu_avail	1	Out	Signal indicating valid bi-level dot data on sfu_hcu_sdata.

25.8.2 Configuration Registers

Table 164. SFU Configuration Registers

Address	register name	#bits	value on reset	description
(SFU_base +)				
Control registers	·	I	<u> </u>	
0x00	Reset	1	0x1	A write to this register causes a reset
	·			of the SFU.
				This register can be read to indicate
				the reset state:
				0 - reset in progress
				1 - reset not in progress
0x04	Go	1	0x0	Writing 1 to this register starts the
				SFU. Writing 0 to this register halts
				the SFU.
				When <i>Go</i> is deasserted the state-
:	1			machines go to their idle states but all
				counters and configuration registers
				keep their values.
				When <i>Go</i> is asserted all counters are
				reset, but configuration registers keep
				their values (i.e. they don't get reset).
				The SFU must be started before the
				LBD is started.
				This register can be read to determine
				if the SFU is running
				(1 - running, 0 - stopped).

25.8.3 SFU sub-block partition

The SFU contains a number of sub-blocks:

Name	description
PCU Interface	PCU interface, configuration and status registers. Also generates the <i>Go</i>
	and the <i>Reset</i> signals for the rest of the SFU
LBD Previous	Contains FIFO which is read by the LBD previous line interface.
Line FIFO	
LBD Next Line	Contains FIFO which is written by the LBD next line interface.
FIFO	
HCU Read Line	Contains FIFO which is read by the HCU interface.
FIFO	
DIU Interface	Contains DIU read interface and DIU write interface. Manages the
and Address	address pointers for the bi-level DRAM buffer. Contains X and Y scaling
Generator	logic.

The various FIFO sub-blocks have no knowledge of where in DRAM their read or write data is stored. In this sense the FIFO sub-blocks are completely de-coupled from the bi-level DRAM buffer. All DRAM address management is centralised in the DIU Interface and Address Generation sub-block. DRAM access is pre-emptive i.e. after a FIFO unit has made an access then as soon as the FIFO has space to read or data to write a DIU access will be requested immediately. This ensures there are no unnecessary stalls introduced e.g. at the end of an LBD or HCU line.

There now follows a description of the SFU sub-blocks.

25.8.4 PCU Interface Sub-block

5

The PCU interface sub-block provides for the CPU to access SFU specific registers by reading or writing to the SFU address space.

25.8.5 LBDPrevLineFIFO sub-block

Table 165. LBDPrevLineFIFO Additional IO Definitions

Port Name	Pins	I/O	Description
Internal Outpu	ıt		
plf_rdy	1	Out	Signal indicating LBDPrevLineFIFO is ready to be read from. Until
			the first <i>lbd_sfu_advline</i> for a band has been received and after the
			number of reads from DRAM for a line is received is equal to
			LBDDRAMWords, plf_rdy is always asserted. During the second
			and subsequent lines <i>plf_rdy</i> is deasserted whenever the
			LBDPrevLineFIFO has one word left in the FIFO
DIU and Addr	ess Gene	eration	sub-block Signals
plf_diurreq	1	Out	Signal indicating the LBDPrevLineFIFO has 256-bits of data free.
plf_diurack	1	ln	Acknowledge that read request has been accepted and plf_diurreq
			should be de-asserted.
plf_diurdata	1	ln-	Data from the DIU to LBDPrevLineFIFO.
			First 64-bits are bits 63:0 of 256 bit word.
			Second 64-bits are bits 127:64 of 256 bit word.
		l	Third 64-bits are bits 191:128 of 256 bit word.
			Fourth 64-bits is are 255:192 of 256 bit word.
plf_diurrvalid	1	ln	Signal indicating data on <i>plf_diurdata</i> is valid.
plf_diuidle	1	Out	Signal indicating DIU state-machine is in the IDLE state.

25.8.5.1 General Description

15

20

The LBDPrevLineFIFO sub-block comprises a double 256-bit buffer between the LBD and the DIU Interface and Address Generator sub-block. The FIFO is implemented as 8 times 64-bit words. The FIFO is written by the DIU Interface and Address Generator sub-block and read by the LBD.

Whenever 4 locations in the FIFO are free the FIFO will request 256-bits of data from the DIU Interface and Address Generation sub-block by asserting *plf_diurreq*. A signal *plf_diurack* indicates that the request has been accepted and *plf_diurreq* should be de-asserted.

The data is written to the FIFO as 64-bits on *plf_diurdata[63:0]* over 4 clock cycles. The signal *plf_diurvalid* indicates that the data returned on *plf_diurdata[63:0]* is valid. *plf_diurvalid* is used to generate the FIFO write enable, *write_en*, and to increment the FIFO write address, *write_adr[2:0]*. If the *LBDPrevLineFIFO* still has 256-bits free then *plf_diurreq* should be asserted again.

The DIU Interface and Address Generation sub-block handles all address pointer management and DIU interfacing and decides whether to acknowledge a request for data from the FIFO. The state diagram of the *LBDPrevLineFIFO* DIU Interface is shown in Figure 163. If *sfu_go* is deasserted then the state-machine returns to its *idle* state.

The LBD reads 16-bit wide data from the *LBDPrevLineFIFO* on *sfu_lbd_pldata[15:0]*. *Ibd_sfu_pladvword* from the LBD tells the *LBDPrevLineFIFO* to supply the next 16-bit word. The FIFO control logic generates a signal *word_select* which selects the next 16-bits of the 64-bit FIFO word to output on *sfu_lbd_pldata[15:0]*. When the entire current 64-bit FIFO word has been read by the LBD *Ibd_sfu_pladvword* will cause the next word to be popped from the FIFO. Previous line data is not supplied until after the first *Ibd_sfu_advline* strobe from the LBD after *sfu_go* is asserted (zero data is supplied instead). Until the first *Ibd_sfu_advline* strobe after

sfu_go lbd_sfu_pladvword strobes are ignored.

The LBDPrevLineFIFO control logic uses a counter, pl_count[7:0], to counts the number of DRAM read accesses for the line. When the pl_count counter is equal to the LBDDRAMWords, a complete line of data has been read by the LBD the plf_rdy is set high, and the counter is reset. It remains high until the next lbd_sfu_advline strobe from the LBD. On receipt of the lbd_sfu_advline strobe the remaining data in the 256-bit word in the FIFO is ignored, and the FIFO read_adr is rounded up if required.

The *LBDPrevLineFIFO* generates a signal *plf_rdy* to indicate that it has data available. Until the first *lbd_sfu_advline* for a band has been received and after the number of DRAM reads for a line is equal to *LBDDRAMWords*, *plf_rdy* is always asserted. During the second and subsequent lines *plf_rdy* is deasserted whenever the *LBDPrevLineFIFO* has one word left.

The last 256-bit word for a line read from DRAM can contain extra padding which should not be output to the LBD. This is because the number of 16-bit words per line may not fit exactly into a 256-bit DRAM word. When the count of the number of DRAM reads for a line is equal to \(\begin{align*} \line \dot{dram_words} & \text{ the LBDPrevLineFIFO} & \text{ must adjust the FIFO write address to point to the next 256-bit word boundary in the FIFO for the next line of data. At the end of a line the read address must round up the nearest 256-bit word boundary and ignore the remaining 16-bit words. This can be achieved by considering the FIFO read address, \(read_adr[2:0] \), will require 3 bits to address 8 locations of 64-bits. The next 256-bit aligned address is calculated by inverting the MSB of the \(read_adr \) and setting all other bits to 0.

40

25.8.6.1 General Description

The LBDNextLineFIFO sub-block comprises a double 256-bit buffer between the LBD and the DIU Interface and Address Generator sub-block. The FIFO is implemented as 8 times 64-bit words. The FIFO is written by the LBD and read by the DIU Interface and Address Generator. Whenever 4 locations in the FIFO are full the FIFO will request 256-bits of data to be written to the DIU Interface and Address Generator by asserting nlf_diuwreq. A signal nlf_diuwack indicates that the request has been accepted and nlf_diuwreq should be de-asserted. On receipt of nlf_diuwack, the data is sent to the DIU Interface as 64-bits on nlf_diuwdata[63:0] over 4 clock cycles. The signal nlf_diuwalid indicates that the data on nlf_diuwdata[63:0] is valid. nlf_diuwvalid should be asserted with the smallest latency after nlf_diuwack. If the LBDNextLineFIFO still has 256-bits more to transfer then nlf_diuwreq should be asserted again. The state diagram of the LBDNextLineFIFO DIU Interface is shown in Figure 166. If sfu_go is deasserted then the state-machine returns to its ldle state.

The signal *nlf_rdy* indicates that the *LBDNextLineFIFO* has space for writing by the LBD. The LBD writes 16-bit wide data supplied on *lbd_sfu_wdata[15:0]*. *lbd_sfu_wvalid* indicates that the data is valid.

The LBDNextLineFIFO control logic counts the number of lbd_sfu_wvalid signals and is used to correctly address into the next line FIFO. The lbd_sfu_wvalid counter is rounded up to the nearest

256-bit word when a *lbd_sfu_advline* strobe is received from the LBD. Any data remaining in the FIFO is flushed to DRAM with padding being added to fill a complete 256-bit word.

25.8.7 sfu_lbd_rdy Generation

5

20

The signal sfu_lbd_rdy is generated by ANDing plf_rdy from the LBDPrevLineFIFO and nlf_rdy from the LBDNextLineFIFO.

sfu_lbd_rdy indicates to the LBD that the SFU is available for writing i.e. there is space available in the LBDNextLineFIFO. After the first lbd_sfu_advline and before the number of lbd_sfu_pladvword strobes received is equivalent to the line length, sfu_lbd_rdy indicates that the SFU is available for both reading, i.e. there is data in the LBDPrevLineFIFO, and writing.

10 Thereafter it indicates the SFU is available for writing.

25.8.8 LBD-SFU Interfaces Timing Waveform Description
In Figure 167 and Figure 168, shows the timing of the data valid and ready signals between the SFU and LBD. A diagram and pseudocode is given for both read and write interfaces between the SFU and LBD.

15 25.8.8.1 LBD-SFU write interface timing

The main points to note from Figure 167 are:

- In clock cycle 1 sfu_lbd_rdy detects that it has only space to receive 2 more 16 bit words from the LBD after the current clock cycle.
- The data on *lbd_sfu_wdata* is valid and this is indicated by *lbd_sfu_wdatavalid* being asserted.
- In clock cycle 2 sfu_lbd_rdy is deasserted however the LBD can not react to this signal until clock cycle 3. So in clock cycle 3 there is also valid data from the LBD which consumes the last available location available in the FIFO in the SFU (FIFO free level is zero).
- In clock cycle 4 and 5 the FIFO is read and 2 words become free in the FIFO.
- In cycle 4 the SFU determines that the FIFO has more room and asserts the ready signal on the next cycle.
 - The LBD has entered a pause mode and waits for sfu_lbd_rdy to be asserted again, in cycle 5 the LBD sees the asserted ready signal and responds by writing one unit into the FIFO, in cycle 6.
- The SFU detects it has 2 spaces left in the FIFO and the current cycle is an active write (same as in cycle 1), and deasserts the ready on the next cycle.
 - In cycle 7 the LBD did not have data to write into the FIFO, and so the FIFO remains with one space left
- The SFU toggles the ready signal every second cycle, this allows the LBD to write one unit at a time to the FIFO.
 - In cycle 9 the LBD responds to the single ready pulse by writing into the FIFO and consuming the last remaining unit free.

The write interface pseudocode for generating the ready is.

```
// ready generation pseudocode

if (fifo_free_level > 2)then
```

```
nlf_rdy = 1
elsif (fifo_free_level == 2) then
    if (lbd_sfu_wdatavalid == 1)then
        nlf_rdy = 0
else
    nlf_rdy = 1
elsif (fifo_free_level == 1) then
    if (lbd_sfu_wdatavalid == 1)then
        nlf_rdy = 0
else
        nlf_rdy = NOT(sfu_lbd_rdy)
else
        nlf_rdy = 0
sfu_lbd_rdy = (nlf_rdy_AND_plf_rdy)
```

15 25.8.8.2 SFU-LBD read interface

The read interface is similar to the write interface except that read data (*sfu_lbd_pldata*) takes an extra cycle to respond to the data advance signal (*lbd_sfu_pladvword* signal).

It is not possible to read the FIFO totally empty during the processing of a line, one word must always remain in the FIFO. At the end of a line the fifo can be read to totally empty. This functionality is controlled by the SFU with the generation of the *plf_rdy* signal.

There is an apparent corner case on the read side which should be highlighted. On examination this turns out to not be an issue.

Scenario 1:

20

25

30

40

sfu_lbd_rdy will go low when there is still is still 2 pieces of data in the FIFO. If there is a lbd_sfu_pladvword pulse in the next cycle the data will appear on sfu_lbd_pldata[15:0].

Scenario 2:

sfu_lbd_rdy will go low when there is still 2 pieces of data in the FIFO. If there is no lbd_sfu_pladvword pulse in the next cycle and it is not the end of the page then the SFU will read the data for the next line from DRAM and the read FIFO will fill more, sfu_lbd_rdy will assert again, and so the data will appear on sfu_lbd_pldata[15:0]. If it happens that the next line of data is not available yet the sfu_lbd_pldata bus will go invalid until the next lines data is available. The LBD does not sample the sfu_lbd_pldata bus at this time (i.e. after the end of a line) and it is safe to have invalid data on the bus.

35 Scenario 3:

sfu_lbd_rdy will go low when there is still 2 pieces of data in the FIFO. If there is no lbd_sfu_pladvword pulse in the next cycle and it is the end of the page then the SFU will do no more reads from DRAM, sfu_lbd_rdy will remain de-asserted, and the data will not be read out from the FIFO. However last line of data on the page is not needed for decoding in the LBD and will not be read by the LBD. So scenario 3 will never apply.

The pseudocode for the read FIFO ready generation

// ready generation pseudocode

```
if (pl_count == lbd_dram_words) then
                   plf_rdy = 1
                 elsif (fifo_fill_level > 3)then
                   plf_rdy = 1
5
                 elsif (fifo_fill_level == 3) then
                   if (lbd_sfu_pladvword == 1)then
                     plf_rdy = 0
                   else
                     plf_rdy = 1
10
                 elsif (fifo_fill_level == 2) then
                   if (lbd_sfu_pladvword == 1)then
                     plf_rdy = 0
                   else
                     plf_rdy = NOT(sfu_lbd_rdy)
15
                 else
                   plf_rdy
                              = 0
                 sfu_lbd_rdy = (plf_rdy AND nlf_rdy)
```

hrf_diuidle	1	Out	Signal indicating DIU state-machine is in the IDLE		
			state.		

25.8.9.1 General Description

The *HCUReadLineFIFO* sub-block comprises a double 256-bit buffer between the HCU and the DIU Interface and Address Generator sub-block. The FIFO is implemented as 8 times 64-bit words. The FIFO is written by the DIU Interface and Address Generator sub-block and read by the HCU.

- The DIU Interface and Address Generation (DAG) sub-block interface of the *HCUReadLineFIFO* is identical to the *LBDPrevLineFIFO* DIU interface.
 - Whenever 4 locations in the FIFO are free the FIFO will request 256-bits of data from the DAG sub-block by asserting *hrf_diurreq*. A signal *hrf_diurack* indicates that the request has been accepted and *hrf_diurreq* should be de-asserted.
- The data is written to the FIFO as 64-bits on hrf_diurvalid indicates that the data returned on hrf_diurvalid indicates that the data returned on hrf_diurvalid is used to generate the FIFO write enable, write_en, and to increment the FIFO write address, write_adr[2:0]. If the HCUReadLineFIFO still has 256-bits free then hrf_diurreq should be asserted again.
- The HCUReadLineFIFO generates a signal sfu_hcu_avail to indicate that it has data available for the HCU. The HCU reads single-bit data supplied on sfu_hcu_sdata. The FIFO control logic generates a signal bit_select which selects the next bit of the 64-bit FIFO word to output on sfu_hcu_sdata. The signal hcu_sfu_advdot tells the HCUReadLineFIFO to supply the next dot (hrf_xadvance = 1) or the current dot (hrf_xadvance = 0) on sfu_hcu_sdata according to the hrf_xadvance signal from the scaling control unit in the DAG sub-block. The HCU should not generate the hcu_sfu_advdot signal until sfu_hcu_avail is true. The HCU can therefore stall
 - When the entire current 64-bit FIFO word has been read by the HCU *hcu_sfu_advdot* will cause the next word to be popped from the FIFO.
- The last 256-bit word for a line read from DRAM and written into the HCUReadLineFIFO can contain dots or extra padding which should not be output to the HCU. A counter in the HCUReadLineFIFO, hcuadvdot_count[15:0], counts the number of hcu_sfu_advdot strobes received from the HCU. When the count equals hcu_num_dots[15:0] the HCUReadLineFIFO must adjust the FIFO read address to point to the next 256-bit word boundary in the FIFO. This can be achieved by considering the FIFO read address, read_adr[2:0], will require 3 bits to address 8 locations of 64-bits. The next 256-bit aligned address is calculated by inverting the MSB of the read_adr and setting all other bits to 0.

waiting for the sfu_hcu_avail signal.

40

The DIU Interface and Address Generator sub-block scaling unit also needs to know when hcuadvdot_count equals hcu_num_dots. This condition is exported from the HCUReadLineFIFO as the signal hrf_hcu_endofline. When the hrf_hcu_endofline is asserted the scaling unit will decide based on vertical scaling whether to go back to the start of the current line or go onto the next line.

25.8.9.2 DRAM Access Limitation

The SFU must output 1 bit/cycle to the HCU. Since *HCUNumDots* may not be a multiple of 256

5 bits the last 256-bit DRAM word on the line can contain extra zeros. In this case, the SFU may not be able to provide 1 bit/cycle to the HCU. This could lead to a stall by the SFU. This stall could then propagate if the margins being used by the HCU are not sufficient to hide it. The maximum stall can be estimated by the calculation: DRAM service period - X scale factor * dots used from last DRAM read for HCU line.

			state.		

25.8.10.1 General Description

The DIU Interface and Address Generator (*DAG*) sub-block manages the bi-level buffer in DRAM. It has a DIU Write Interface for the *LBDNextLineFIFO* and a DIU Read Interface shared between the *HCUReadLineFIFO* and *LBDPrevLineFIFO*.

All DRAM address management is centralised in the *DAG*. DRAM access is pre-emptive i.e. after a FIFO unit has made an access then as soon as the FIFO has space to read or data to write a DIU access will be requested immediately. This ensures there are no unnecessary stalls introduced e.g. at the end of an LBD or HCU line.

The control logic for horizontal and vertical non-integer scaling logic is completely contained in the DAG sub-block. The scaling control unit exports the hlf_xadvance signal to the HCUReadLineFIFO which indicates whether to replicate the current dot or supply the next dot for horizontal scaling.

25.8.10.2 DIU Write Interface

The LBDNextLineFIFO generates all the DIU write interface signals directly except for

sfu_diu_wadr[21:5] which is generated by the Address Generation logic

The DIU request from the LBDNextLineFIFO will be negated if its respective address pointer in

DRAM is invalid i.e. nlf_adrvalid = 0. The implementation must ensure that no erroneous requests occur on sfu_diu_wreq.

25.8.10.3 DIU Read Interface

Both *HCUReadLineFIFO* and *LBDPrevLineFIFO* share the read interface. If both sources request simultaneously, then the arbitration logic implements a round-robin sharing of read accesses between the *HCUReadLineFIFO* and *LBDPrevLineFIFO*.

The DIU read request arbitration logic generates a signal, <code>select_hrfplf</code>, which indicates whether the DIU access is from the <code>HCUReadLineFIFO</code> or <code>LBDPrevLineFIFO</code> (0=<code>HCUReadLineFIFO</code>, 1 = <code>LBDPrevLineFIFO</code>). Figure 171 shows <code>select_hrfplf</code> multiplexing the returned DIU acknowledge and read data to either the <code>HCUReadLineFIFO</code> or <code>LBDPrevLineFIFO</code>.

The DIU read request arbitration logic is shown in Figure 172. The arbitration logic will select a DIU read request on hrf_diurreq or plf_diurreq and assert sfu_diu_rreq which goes to the DIU. The accompanying DIU read address is generated by the Address Generation Logic. The select signal select_hrfplf will be set according to the arbitration winner (0=HCUReadLineFIFO, 1=LBDPrevLineFIFO). sfu_diu_rreq is cleared when the DIU acknowledges the request on diu_sfu_rack. Arbitration cannot take place again until the DIU state-machine of the arbitration winner is in the idle state, indicated by diu_idle. This is necessary to ensure that the DIU read data is multiplexed back to the FIFO that requested it.

The DIU read requests from the *HCUReadLineFIFO* and *LBDPrevLineFIFO* will be negated if their respective addresses in DRAM are invalid, *hrf_adrvalid* = 0 or *plf_adrvalid* = 0. The implementation must ensure that no erroneous requests occur on *sfu_diu_rreq*.

If the HCUReadLineFIFO and LBDPrevLineFIFO request simultaneously, then if the request is not following immediately another DIU read port access, the arbitration logic will choose the HCUReadLineFIFO by default. If there are back to back requests to the DIU read port then the arbitration logic implements a round-robin sharing of read accesses between the

20 HCUReadLineFIFO and LBDPrevLineFIFO.

15

A pseudo-code description of the DIU read arbitration is given below.

```
history is
                                    of type
                                               {none, hrf, plf},
                                                                     hrf
                                                                          is
                HCUReadLineFIFO, plf is LBDPrevLineFIFO
25
                   // initialisation on reset
                   select_hrfplf = 0 // default choose hrf
                  history = none // no DIU read access immediately preceding
                  // state-machine is busy between asserting sfu diu rreq
30
                 and diu\ idle = 1
                   // if DIU read requester state-machine is in idle state
                 then de-assert busy
                   if (diu_idle == 1) then
                     busy = 0
35
                   //if acknowledge received from DIU then de-assert DIU
                 request
                   if (diu sfu rack == 1) then
                     //de-assert request in response to acknowledge
40
                     sfu diu rreq = 0
                   // if not busy then arbitrate between incoming requests
                   // if request detected then assert busy
```

```
if (busy == 0) then
                     //if there is no request
                     if (hrf_diurreq == 0) AND (plf_diurreq == 0) then
                        sfu diu rreq = 0

                          elsif (history == plf) then
                               history = hrf
40
                            select hrfplf = 0
                        // end there is a request
```

25.8.10.4 Address Generation Logic

The DIU interface generates the DRAM addresses of data read and written by the SFU's FIFOs.

A write request from the *LBDNextLineFIFO* on *nlf_diuwreq* causes a write request from the DIU Write Interface. The Address Generator supplies the DRAM write address on *sfu_diu_wadr[21:5]*.

A winning read request from the DIU read request arbitration logic causes a read request from the DIU Read Interface. The Address Generator supplies the DRAM read address on $sfu_diu_radr[21:5]$.

The address generator is configured with the number of DRAM words to read in a HCU line,

- 5 hcu_dram_words, the first DRAM address of the SFU area, start_sfu_adr[21:5], and the last DRAM address of the SFU area, end_sfu_adr[21:5].
 - Note *hcu_dram_words* configuration register specifies the number of DRAM words consumed per line in the HCU, while *lbd_dram_words* specifies the number of DRAM words generated per line by the LBD. These values are not required to be the same.
- 10 For example the LBD may store 10 DRAM words per line (*lbd_dram_words* = 10), but the HCU may consume 5 DRAM words per line. In such case the *hcu_dram_words* would be set to 5 and the HCU Read Line FIFO would trigger a new line after it had consumed 5 DRAM words (via *hrf_hcu_endofline*).

Address Generation

- 15 There are four address pointers used to manage the bi-level DRAM buffer:
 - a. hcu_readline_rd_adr is the read address in DRAM for the HCUReadLineFIFO.
 - b. hcu_startreadline_adr is the start address in DRAM for the current line being read by the HCUReadLineFIFO.
 - c. Ibd_nextline_wr_adr is the write address in DRAM for the LBDNextLineFIFO.
- d. *lbd_prevline_rd_adr* is the read address in DRAM for the *LBDPrevLineFIFO*.

The current value of these address pointers are readable by the CPU.

Four corresponding address valid flags are required to indicate whether the address pointers are valid, based on whether the FIFOs are full or empty.

- a. hlf_adrvalid, derived from hrf_nlf_fifo_emp
- 25 b. hlf_start_adrvalid, derived from start_hrf_nlf_fifo_emp
 - c. nlf_adrvalid. derived from nlf_plf_fifo_full and nlf_hrf_fifo_full
 - d. plf_adrvalid. derived from plf_nlf_fifo_emp

DRAM requests from the FIFOs will not be issued to the DIU until the appropriate address flag is valid.

Once a request has been acknowledged, the address generation logic can calculate the address of the next 256-bit word in DRAM, ready for the next request.

Rules for address pointers

35

40

The address pointers must obey certain rules which indicate whether they are valid:

- a. hcu_readline_rd_adr is only valid if it is reading earlier in the line than lbd_nextline_wr_adr is writing i.e. the fifo is not empty
 - b. The SFU (*lbd_nextline_wr_adr*) cannot overwrite the current line that the HCU is reading from (*hcu_startreadline_adr*) i.e. the fifo is not full, when compared with the HCU read line pointer
 - c. The LBDNextLineFIFO (lbd_nextline_wr_adr) must be writing earlier in the line than LBD-PrevLineFIFO (lbd_prevline_rd_adr) is reading and must not overwrite the current line that the HCU is reading from i.e. the fifo is not full when compared to the PrevLineFifo read pointer

- d. The LBDPrevLineFIFO (lbd_prevline_rd_adr) can read right up to the address that LBDNext-LineFIFO (lbd_nextline_wr_adr) is writing i.e the fifo is not empty.
- e. At startup i.e. when sfu_go is asserted, the pointers are reset to start_sfu_adr[21:5].
- f. The address pointers can wrap around the SFU bi-level store area in DRAM.
- 5 Address generator pseudo-code:

```
Initialization:
                 if (sfu go rising edge) then
                    //initialise address pointers to start of SFU address
                 space
10
                   lbd prevline rd adr
                                                   = start sfu adr[21:5]
                   lbd_nextline_wr_adr
                                                   = start sfu adr[21:5]
                   hcu readline rd adr
                                                   = start sfu adr[21:5]
                   hcu startreadline_adr
                                                   = start sfu adr[21:5]
                   lbd_nextline_wr_wrap
15
                   lbd prevline rd wrap
                   hcu startreadline wrap
                   hcu readline rd wrap
                                                   = 0
                   }
                 Determine FIFO fill and empty status:
20
                 // calculate which FIFOs are full and empty
                 plf nlf fifo emp
                                            (lbd_prevline rd adr
                 lbd nextline wr adr) AND
                                      (lbd_prevline_rd_wrap
                 lbd_nextline wr wrap)
25
                 nlf plf fifo full
                                           (lbd nextline_wr_adr
                 lbd_prevline_rd_adr) AND
                                      (lbd prevline rd wrap
                 lbd nextline_wr_wrap)
                 nlf hrf fifo full
                                           (lbd nextline wr adr
30
                 hcu_startreadline_adr ) AND
                                      (hcu_startreadline_wrap

25.8.10.4.1 X scaling of data for HCUReadLineFIFO

25

The signal hcu_sfu_advdot tells the HCUReadLineFIFO to supply the next dot or the current dot on sfu_hcu_sdata according to the hrf_xadvance signal from the scaling control unit. When hrf_xadvance is 1 the HCUReadLineFIFO should supply the next dot. When hrf_xadvance is 0 the HCUReadLineFIFO should supply the current dot.

The algorithm for non-integer scaling is described in the pseudocode below. Note, x_scale_count should be loaded with x_start_count after reset and at the end of each line. The end of the line is indicated by $hrf_hcu_endofline$ from the HCUReadLineFIFO.

The HCUReadLineFIFO counts the number of hcu_sfu_advdot strobes received from the HCU. When the count equals hcu_num_dots the HCUReadLineFIFO will assert hrf_hcu_endofline for a cycle.

The algorithm for non-integer scaling is described in the pseudocode below. Note, *y_scale_count* should be loaded with zero after reset.

When the *hrf_hcu_endofline* is asserted the Y scaling unit will decide whether to go back to the start of the current line, by setting *hrf_yadvance* = 0, or go onto the next line, by setting *hrf_yadvance* = 1.

Figure 176 shows an overview of X and Y scaling for HCU data.

26 Tag Encoder (TE)

25 26.1 OVERVIEW

30

35

5

The Tag Encoder (TE) provides functionality for Netpage-enabled applications, and typically requires the presence of IR ink (although K ink can be used for tags in limited circumstances). The TE encodes fixed data for the page being printed, together with specific tag data values into an error-correctable encoded tag which is subsequently printed in infrared or black ink on the page. The TE places tags on a triangular grid, and can be programmed for both landscape and portrait orientations.

Basic tag structures are normally rendered at 1600 dpi, while tag data is encoded into an arbitrary number of printed dots. The TE supports integer scaling in the Y-direction while the TFU supports integer scaling in the X-direction. Thus, the TE can render tags at resolutions less than 1600 dpi which can be subsequently scaled up to 1600 dpi.

The output from the TE is buffered in the Tag FIFO Unit (TFU) which is in turn used as input by the HCU. In addition, a *te_finishedband* signal is output to the end of band unit once the input tag data has been loaded from DRAM. The high level data path is shown by the block diagram in Figure 177.

After passing through the HCU, the tag plane is subsequently printed with an infrared-absorptive ink that can be read by a Netpage sensing device. Since black ink can be IR absorptive, limited functionality can be provided on offset-printed pages using black ink on otherwise blank areas of

the page - for example to encode buttons. Alternatively an invisible infrared ink can be used to print the position tags over the top of a regular page. However, if invisible IR ink is used, care must be taken to ensure that any other printed information on the page is printed in infrared-transparent CMY ink, as black ink will obscure the infrared tags. The monochromatic scheme was chosen to maximize dynamic range in blurry reading environments.

When multiple SoPEC chips are used for printing the same side of a page, it is possible that a single tag will be produced by two SoPEC chips. This implies that the TE must be able to print partial tags.

The throughput requirement for the SoPEC TE is to produce tags at half the rate of the PEC1 TE.

Since the TE is reused from PEC1, the SoPEC TE over-produces by a factor of 2.

In PEC1, in order to keep up with the HCU which processes 2 dots per cycle, the tag data interface has been designed to be capable of encoding a tag in 63 cycles. This is actually accomplished in approximately 52 cycles within PEC1. If the SoPEC TE were to be modified from two dots production per cycle to a nominal one dot per cycle it should not lose the 63/52 cycle performance edge attained in the PEC1 TE.

26.2 WHAT ARE TAGS?

5

20

25

30

35

40

The first barcode was described in the late 1940's by Woodland and Silver, and finally patented in 1952 (US Patent 2,612,994) when electronic parts were scarce and very expensive. Now however, with the advent of cheap and readily available computer technology, nearly every item purchased from a shop contains a barcode of some description on the packaging. From books to CDs, to grocery items, the barcode provides a convenient way of identifying an object by a product number. The exact interpretation of the product number depends on the type of barcode. Warehouse inventory tracking systems let users define their own product number ranges, while inventory in shops must be more universally encoded so that products from one company don't overlap with products from another company. Universal Product Codes (UPC) were introduced in the mid 1970's at the request of the National Association of Food Chains for this very reason. Barcodes themselves have been specified in a large number of formats. The older barcode formats contain characters that are displayed in the form of lines. The combination of black and white lines describe the information the barcodes contains. Often there are two types of lines to form the complete barcode: the characters (the information itself) and lines to separate blocks for better optical recognition. While the information may change from barcode to barcode, the lines to separate blocks stays constant. The lines to separate blocks can therefore be thought of as part of the constant structural components of the barcode.

Barcodes are read with specialized reading devices that then pass the extracted data onto the computer for further processing. For example, a point-of-sale scanning device allows the sales assistant to add the scanned item to the current sale, places the name of the item and the price on a display device for verification etc. Light-pens, gun readers, scanners, slot readers, and cameras are among the many devices used to read the barcodes.

To help ensure that the data extracted was read correctly, checksums were introduced as a crude form of error detection. More recent barcode formats, such as the Aztec 2D barcode developed by

Andy Longacre in 1995 (US patent number US5591956), but now released to the public domain, use redundancy encoding schemes such as Reed-Solomon. Reed Solomon encoding is adequately discussed in [28], [30] and [34]. The reader is advised to refer to these sources for background information. Very often the degree of redundancy encoding is user selectable.

More recently there has also been a move from the simple one dimensional barcodes (line based) to two dimensional barcodes. Instead of storing the information as a series of lines, where the data can be extracted from a single dimension, the information is encoded in two dimensions. Just as with the original barcodes, the 2D barcode contains both information and structural components for better optical recognition. Figure 178 shows an example of a QR Code (Quick Response Code), developed by Denso of Japan (US patent number US5726435). Note the barcode cell is comprised of two areas: a data area (depends on the data being stored in the

barcode cell is comprised of two areas: a data area (depends on the data being stored in the barcode), and a constant position detection pattern. The constant position detection pattern is used by the reader to help locate the cell itself, then to locate the cell boundaries, to allow the reader to determine the original orientation of the cell (orientation can be determined by the fact

that there is no 4th corner pattern).

The number of barcode encoding schemes grows daily. Yet very often the hardware for producing these barcodes is specific to the particular barcode format. As printers become more and more embedded, there is an increasing desire for real-time printing of these barcodes. In particular, Netpage enabled applications require the printing of 2D barcodes (or tags) over the page, preferably in infra-red ink. The tag encoder in SoPEC uses a generic barcode format encoding scheme which is particularly suited to real-time printing. Since the barcode encoding format is generic, the same rendering hardware engine can be used to produce a wide variety of barcode

formats.

Unfortunately the term "barcode" is interpreted in different ways by different people. Sometimes it refers only to the data area component, and does not include the constant position detection pattern. In other cases it refers to both data and constant position detection pattern.

We therefore use the term *tag* to refer to the combination of data and any other components (such as position detection pattern, blank space etc. surround) that must be rendered to help hold or locate/read the data. A tag therefore contains the following components:

30

35

15

20

25

- data area(s). The data area is the whole reason that the tag exists. The tag data area(s) contains the encoded data (optionally redundancy-encoded, perhaps simply checksummed) where the bits of the data are placed within the data area at locations specified by the tag encoding scheme.
- constant background patterns, which typically includes a constant position detection
 pattern. These help the tag reader to locate the tag. They include components that are easy
 to locate and may contain orientation and perspective information in the case of 2D tags.
 Constant background patterns may also include such patterns as a blank area surrounding
 the data area or position detection pattern. These blank patterns can aid in the decoding of
 the data by ensuring that there is no interference between tags or data areas.

In most tag encoding schemes there is at least some constant background pattern, but it is not necessarily required by all. For example, if the tag data area is enclosed by a physical space and the reading means uses a non-optical location mechanism (e.g. physical alignment of surface to data reader) then a position detection pattern is not required.

- Different tag encoding schemes have different sized tags, and have different allocation of physical tag area to constant position detection pattern and data area. For example, the QR code has 3 fixed blocks at the edges of the tag for position detection pattern (see Figure 178) and a data area in the remainder. By contrast, the Netpage tag structure (see Figures 179 and 180) contains a circular locator component, an orientation feature, and several data areas. Figure 179(a) shows the Netpage tag constant background pattern in a resolution independent form. Figure 179(b) is the same as Figure 179(a), but with the addition of the data areas to the Netpage tag. Figure 180 is an example of dot placement and rendering to 1600 dpi for a Netpage tag. Note that in Figure 180 a single bit of data is represented by many physical output dots to form a block within the data area.
- 15 26.2.1 Contents of the data area

20

The data area contains the data for the tag.

Depending on the tag's encoding format, a single bit of data may be represented by a number of physical printed dots. The exact number of dots will depend on the output resolution and the target reading/scanning resolution. For example, in the QR code (see Figure 178), a single bit is represented by a dark module or a light module, where the exact number of dots in the dark module or light module depends on the rendering resolution and target reading/scanning resolution. For example, a dark module may be represented by a square block of printed dots (all on for binary 1, or all off for binary 0), as shown in Figure 181.

The point to note here is that a single bit of data may be represented in the printed tag by an arbitrary printed shape. The smallest shape is a single printed dot, while the largest shape is theoretically the whole tag itself, for example a giant *macrodot* comprised of many printed dots in both dimensions.

An ideal generic tag definition structure allows the generation of an arbitrary printed shape from each bit of data.

30 26.2.2 What do the bits represent?

Given an original number of bits of data, and the desire to place those bits into a printed tag for subsequent retrieval via a reading/scanning mechanism, the original number of bits can either be placed directly into the tag, or they can be redundancy-encoded in some way. The exact form of redundancy encoding will depend on the tag format.

The placement of data bits within the data area of the tag is directly related to the redundancy mechanism employed in the encoding scheme. The idea is generally to place data bits together in 2D so that burst errors are averaged out over the tag data, thus typically being correctable. For example, all the bits of Reed-Solomon codeword would be spread out over the entire tag data area so to minimize being affected by a burst error.

Since the data encoding scheme and shape and size of the tag data area are closely linked, it is desirable to have a generic tag format structure. This allows the same data structure and rendering embodiment to be used to render a variety of tag formats.

26.2.2.1 Fixed and variable data components

10

15

25

40

In many cases; the tag data can be reasonably divided into fixed and variable components. For example, if a tag holds *N* bits of data, some of these bits may be fixed for all tags while some may vary from tag to tag.

For example, the Universal product code allows a country code and a company code. Since these bits don't change from tag to tag, these bits can be defined as fixed, and don't need to be provided to the tag encoder each time, thereby reducing the bandwidth when producing many tags.

Another example is Netpage tags. A single printed page contains a number of Netpage tags. The page-id will be constant across all the tags, even though the remainder of the data within each tag may be different for each tag. By reducing the amount of variable data being passed to SoPEC's tag encoder for each tag, the overall bandwidth can be reduced.

Depending on the embodiment of the tag encoder, these parameters will be either implicit or explicit, and may limit the size of tags renderable by the system. For example, a software tag encoder may be completely variable, while a hardware tag encoder such as SoPEC's tag encoder may have a maximum number of tag data bits.

20 26.2.2.2 Redundancy-encode the tag data within the tag encoder

Instead of accepting the complete number of TagData bits encoded by an external encoder, the tag encoder accepts the basic non-redundancy-encoded data bits and encodes them as required for each tag. This leads to significant savings of bandwidth and on-chip storage.

In SoPEC's case for Netpage tags, only 120 bits of original data are provided per tag, and the tag encoder encodes these 120 bits into 360 bits. By having the redundancy encoder on board the tag encoder the effective bandwidth and internal storage required is reduced to only 33% of what would be required if the encoded data was read directly.

26.3 PLACEMENT OF TAGS ON A PAGE

The TE places tags on the page in a triangular grid arrangement as shown in Figure 182.

The triangular mesh of tags combined with the restriction of no overlap of columns or rows of tags means that the process of tag placement is greatly simplified. For a given line of dots, all the tags on that line correspond to the same part of the general tag structure. The triangular placement can be considered as alternative lines of tags, where one line of tags is inset by one amount in the dot dimension, and the other line of dots is inset by a different amount. The dot inter-tag gap is the same in both lines of tag, and is different from the line inter-tag gap.

Note also that as long as the tags themselves can be rotated, portrait and landscape printing are essentially the same - the placement parameters of line and dot are swapped, but the placement mechanism is the same.

The general case for placement of tags therefore relies on a number of parameters, as shown in Figure 183.

The parameters are more formally described in Table 169. Note that these are placement parameters and not registers.

Table 169. Tag placement parameters

parameter	description	restrictions
Tag height	The number of dot lines in a tag's bounding box	minimum 1
Tag width	The number of dots in a single line of the tag's bounding	minimum 1
	box. The number of dots in the tag itself may vary	
	depending on the shape of the tag, but the number of dots	
	in the bounding box will be constant (by definition).	
Dot inter-tag gap	The number of dots from the edge of one tag's bounding	minimum = 0
	box to the start of the next tag's bounding box, in the dot	
	direction.	
Line inter-tag	The number of dot lines from the edge of one tag's	minimum = 0
gap	bounding box to the start of the next tag's bounding box, in	
	the line direction.	
Start Position	Defines the status of the top left dot on the page - is an	-
	offset in dot & row within the tag or the inter-tag gap.	
AltTagLinePositi	Defines the status for the start of the alternate row of tags.	-
on	ls an offset in dot within the tag or within the dot inter-tag	
	gap (the row position is always 0).	

5 26.4 BASIC TAG ENCODING PARAMETERS

10

SoPEC's tag encoder imposes range restrictions on tag encoding parameters as a direct result of on-chip buffer sizes. Table 170 lists the basic encoding parameters as well as range restrictions where appropriate. Although the restrictions were chosen to take the most likely encoding scenarios into account, it is a simple matter to adjust the buffer sizes and corresponding addressing to allow arbitrary encoding parameters in future implementations.

Table 170. Encoding parameters

name	definition	maximum value imposed by TE
W	page width	2 ¹⁴ dotpairs or 20.48 inches at 1600 dpi
S		typical tag size is 2mm × 2mm maximum tag size is 384 dots x 384 dots before scaling i.e. 6 mm x 6 mm at 1600 dpi
N	number of dots in each dimension of the tag	384 dots before scaling
E	redundancy encoding for tag data	Reed-Solomon GF(2 ⁴) at 5:10 or 7:8
D_{F}	size of fixed data (unencoded)	40 or 56 bits
R _F	size of redundancy-encoded fixed	120 bits

	data	
$\overline{D_{V}}$	size of variable data (unencoded)	120 or 112 bits
R√	size of redundancy-encoded variate	ble 360 or 240 bits
	data	
T	tags per page width	256

The fixed data for the tags on a page need only be supplied to the TE once. It can be supplied as 40 or 56 bits of unencoded data and encoded within the TE as described in Section 26.4.1.

Alternatively it can be supplied as 120 bits of pre-encoded data (encoded arbitrarily).

The variable data for the tags on a page are those 112 or 120 data bits that are variable for each tag. Variable tag data is supplied as part of the band data, and is always encoded by the TE as described in Section 26.4.1, but may itself be arbitrarily pre-encoded.

26.4.1 Redundancy encoding

5

10

20

The mapping of data bits (both fixed and variable) to redundancy encoded bits relies heavily on the method of redundancy encoding employed. Reed-Solomon encoding was chosen for its ability to deal with burst errors and effectively detect and correct errors using a minimum of redundancy. Reed Solomon encoding is adequately discussed in [28], [30] and [34]. The reader is advised to refer to these sources for background information.

In this implementation of the TE we use Reed-Solomon encoding over the Galois Field GF(2⁴). Symbol size is 4 bits. Each codeword contains 15 4-bit symbols for a codeword length of 60 bits.

- The primitive polynomial is $p(x) = x^4 + x + 1$, and the generator polynomial is $g(x) = (x+\alpha)(x+\alpha^2)...(x+\alpha^{2t})$, where t = the number of symbols that can be corrected.

 Of the 15 symbols, there are two possibilities for encoding:
 - RS(15, 5): 5 symbols original data (20 bits), and 10 redundancy symbols (40 bits). The 10 redundancy symbols mean that we can correct up to 5 symbols in error. The generator polynomial is therefore $g(x) = (x+\alpha)(x+\alpha^2)...(x+\alpha^{10})$.
 - RS(15, 7): 7 symbols original data (28 bits), and 8 redundancy symbols (32 bits). The 8 redundancy symbols mean that we can correct up to 4 symbols in error. The generator polynomial is $g(x) = (x+\alpha)(x+\alpha^2)...(x+\alpha^8)$.

In the first case, with 5 symbols of original data, the total amount of original data per tag is 160 bits (40 fixed, 120 variable). This is redundancy encoded to give a total amount of 480 bits (120 fixed, 360 variable) as follows:

- Each tag contains up to 40 bits of fixed original data. Therefore 2 codewords are required
 for the fixed data, giving a total encoded data size of 120 bits. Note that this fixed data only
 needs to be encoded once per page.
- Each tag contains up to 120 bits of variable original data. Therefore 6 codewords are required for the variable data, giving a total encoded data size of 360 bits.

In the second case, with 7 symbols of original data, the total amount of original data per tag is 168 bits (56 fixed, 112 variable). This is redundancy encoded to give a total amount of 360 bits (120 fixed, 240 variable) as follows:

- Each tag contains up to 56 bits of fixed original data. Therefore 2 codewords are required
 for the fixed data, giving a total encoded data size of 120 bits. Note that this fixed data only
 needs to be encoded once per page.
- Each tag contains up to 112 bits of variable original data. Therefore 4 codewords are required for the variable data, giving a total encoded data size of 240 bits.

The choice of data to redundancy ratio depends on the application.

26.5 DATA STRUCTURES USED BY TAG ENCODER

26.5.1 Tag Format Structure

5

15

20

25

35

The Tag Format Structure (TFS) is the template used to render tags, optimized so that the tag can be rendered in real time. The TFS contains an entry for each dot position within the tag's bounding box. Each entry specifies whether the dot is part of the constant background pattern or part of the tag's data component (both fixed and variable).

The TFS is very similar to a bitmap in that it contains one entry for each dot position of the tag's bounding box. The TFS therefore has *TagHeight* × *TagWidth* entries, where *TagHeight* matches the height of the bounding box for the tag in the line dimension, and *TagWidth* matches the width of the bounding box for the tag in the dot dimension. A single line of TFS entries for a tag is known as a *tag line structure*.

The TFS consists of *TagHeight* number of *tag line structures*, one for each 1600 dpi line in the tag's bounding box. Each tag line structure contains three contiguous tables, known as tables A, B, and C. Table A contains 384 2-bit entries, one entry for each of the maximum number of dots in a single line of a tag (see Table). The actual number of entries used should match the size of the bounding box for the tag in the dot dimension, but all 384 entries must be present. Table B contains 32 9-bit data addresses that refer to (in order of appearance) the data dots present in the particular line. All 32 entries must be present, even if fewer are used. Table C contains two 5-bit pointers into table B, and therefore comprises 10 bits. Padding of 214 bits is added. The total length of each tag line structure is therefore 5 × 256-bit DRAM words. Thus a TFS containing *TagHeight* tag line structures requires a *TagHeight* * 160 bytes. The structure of a TFS is shown in Figure 184.

A full description of the interpretation and usage of Tables A, B and C is given in section 26.8.3 on page 444.

26.5.1.1 Scaling a tag

If the size of the printed dots is too small, then the tag can be scaled in one of several ways. Either the tag itself can be scaled by N dots in each dimension, which increases the number of entries in the TFS. As an alternative, the output from the TE can be scaled up by pixel replication via a scale factor greater than 1 in the both the TE and TFU.

For example, if the original TFS was 21×21 entries, and the scaling were a simple 2×2 dots for each of the original dots, we could increase the TFS to be 42×42 . To generate the new TFS from the old, we would repeat each entry across each line of the TFS, and then we would repeat each line of the TFS. The net number of entries in the TFS would be increased fourfold (2×2) .

The TFS allows the creation of *macrodots* instead of simple scaling. Looking at Figure 185 for a simple example of a 3×3 dot tag, we may want to produce a physically large printed form of the tag, where each of the original dots was represented by 7×7 printed dots. If we simply performed replication by 7 in each dimension of the original TFS, either by increasing the size of the TFS by 7 in each dimension or putting a scale-up on the output of the tag generator output, then we would have 9 sets of 7×7 square blocks. Instead, we can replace each of the original dots in the TFS by a 7×7 dot definition of a rounded dot. Figure 186 shows the results.

Consequently, the higher the resolution of the TFS the more printed dots can be printed for each macrodot, where a macrodot represents a single data bit of the tag. The more dots that are available to produce a macrodot, the more complex the pattern of the macrodot can be. As an example, Figure n page 461 on page **Error! Bookmark not defined.** shows the Netpage tag structure rendered such that the data bits are represented by an average of 8 dots \times 8 dots (at 1600 dpi), but the actual shape structure of a dot is not square. This allows the printed Netpage tag to be subsequently read at any orientation.

15 26.5.2 Raw tag data

5

10

20

25

35

The TE requires a band of unencoded variable tag data if variable data is to be included in the tag bit-plane. A band of unencoded variable tag data is a set of contiguous unencoded tag data records, in order of encounter top left of printed band from top left to lower right.

An unencoded tag data record is 128 bits arranged as follows: bits 0-111 or 0-119 are the bits of raw tag data, bit 120 is a flag used by the TE (*TagIsPrinted*), and the remaining 7 bits are reserved (and should be 0). Having a record size of 128 bits simplifies the tag data access since the data of two tags fits into a 256-bit DRAM word. It also means that the flags can be stored apart from the tag data, thus keeping the raw tag data completely unrestricted. If there is an odd number of tags in line then the last DRAM read will contain a tag in the first 128 bits and padding in the final 128 bits.

The *TaglsPrinted* flag allows the effective specification of a tag resolution mask over the page. For each tag position the *TaglsPrinted* flag determines whether any of the tag is printed or not. This allows arbitrary placement of tags on the page. For example, tags may only be printed over particular active areas of a page. The *TaglsPrinted* flag allows only those tags to be printed.

30 TagIsPrinted is a 1 bit flag with values as shown in Table 171.

Table 171. TagIsPrinted values

Value	description
o	Don't print the tag in this tag position.
	Output 0 for each dot within the tag bounding box.
1	Print the tag as specified by the various tag structures.

26.5.3 DRAM storage requirements

The total DRAM storage required by a single band of raw tag data depends on the number of tags present in that band. Each tag requires 128 bits. Consequently if there are *N* tags in the band, the size in DRAM is 16N bytes.

The maximum size of a line of tags is 163×128 bits. When maximally packed, a row of tags contains 163 tags (see Table) and extends over a minimum of 126 print lines. This equates to 282 KBytes over a Letter page.

The total DRAM storage required by a single TFS is TagHeight/7 KBytes (including padding).

- 5 Since the likely maximum value for *TagHeight* is 384 (given that SoPEC restricts *TagWidth* to 384), the maximum size in DRAM for a TFS is 55 KBytes.
 - 26.5.4 DRAM access requirements

The TE has two separate read interfaces to DRAM for raw tag data, TD, and tag format structure, TFS.

The memory usage requirements are shown in Table 172. Raw tag data is stored in the compressed page store

Table 172. Memory usage requirements

Block	Size	Description
Compressed page	2048 Kbytes	Compressed data page store for Bi-
store		level, contone and
		raw tag data.
Tag Format Structure	55 Kbyte (384 dot line	55 kB in PEC1 for 384 dot line tags (the
	tags @ 1600 dpi)	benchmark) at 1600 dpi
		2.5 mm tags (1/10th inch) @ 1600 dpi
		require 160 dot lines = 160/384 x55 or
		23 kB
		2.5 mm tags @ 800 dpi require 80/384
		x55 = 12 kB

The TD interface will read 256-bits from DRAM at a time. Each 256-bit read returns 2 times 128-bit tags. The TD interface to the DIU will be a 256-bit double buffer. If there is an odd number of tags in line then the last DRAM read will contain a tag in the first 128 bits and padding in the final 128 bits.

The TFS interface will also read 256-bits from DRAM at a time. The TFS required for a line is 136 bytes. A total of 5 times 256-bit DRAM reads is required to read the TFS for a line with 192 unused bits in the fifth 256-bit word. A 136-byte double-line buffer will be implemented to store the TFS data.

The TE's DIU bandwidth requirements are summarized in Table 173.

Table 173. DRAM bandwidth requirements

Block Name Direction Maximum number of Peak Bandwidth Average cycles between each (bits/cycle) Bandwidth (bits/cycle)

20

TD	Read	Single 256 bit reads1.	1.02	1.02
TFS	Read	Single 256 bit reads2. TFS is 136	0.093	0.093
		bytes. This means there is unused	4	
	1	data in the fifth 256 bit read. A		
		total of 5 reads is required.		

- 1: Each 2mm tag lasts 126 dot cycles and requires 128 bits. This is a rate of 256 bits every 252 cycles.
- 2: 17×64 bit reads per line in PEC1 is 5×256 bit reads per line in SoPEC with unused bits in the last 256-bit read.
- 26.5.5 TD and TFS Bandstore wrapping

Table 174. Bandstore Inputs from CDU

Port Name	Pins	1/0	Description
cdu_endofbandstore[21:	17	In	Address of the end of the current band of data.
5]			256-bit word aligned DRAM address.
cdu_startofbandstore[21:	17	In	Address of the start of the current band of data.
5]			256-bit word aligned DRAM address.

Both TD and TFS storage in DRAM can wrap around the bandstore area. The bounds of the band store are described by inputs from the CDU shown in Table 174. The TD and TFS DRAM interfaces therefore support bandstore wrapping. If the TD or TFS DRAM interface increments an address it is checked to see if it matches the end of bandstore address. If so, then the address is mapped to the start of the bandstore.

26.5.6 Tag sizes

5

10

- SoPEC allows for tags to be between 0 to 384 dots. A typical 2 mm tag requires 126 dots. Short tags do not change the internal bandwidth or throughput behaviours at all. Tag height is specified so as to allow the DRAM storage for raw tag data to be specified. Minimum tag width is a condition imposed by throughput limitations, so if the width is too small TE cannot consistently produce 2 dots per cycle across several tags (also there are raw tag data bandwidth implications).
- Thinner tags still work, they just take longer and/or need scaling.
 - 26.6 IMPLEMENTATION
 - 26.6.1 Tag Encoder Architecture

A block diagram of the TE can be seen below.

The TE writes lines of bi-level tag plane data to the TFU for later reading by the HCU. The TE is
responsible for merging the encoded tag data with the tag structure (interpreted from the TFS). Yinteger scaling of tags is performed in the TE with X-integer scaling of the tags performed in the
TFU. The encoded tag layer is generated 2 bits at a time and output to the TFU at this rate. The
HCU however only consumes 1 bit per cycle from the TFU. The TE must provide support for
126dot Tags (2mm densely packed) with 108 Tags per line with 128bits per tag.

The tag encoder consists of a TFS interface that loads and decodes TFS entries, a tag data interface that loads tag raw data, encodes it, and provides bit values on request, and a state machine to generate appropriate addressing and control signals. The TE has two separate read interfaces to DRAM for raw tag data, TD, and tag format structure, TFS.

- It is possible that the raw tag data interface, the TD, to the DIU could be replaced by a hardware state machine at a later stage. This would allow flexibility in the generation of tags. Support for Y scaling needs to be added to the PEC1 TE. The PEC1 TE already allows stalling at its output during a line when tfu_te_oktowrite is deasserted.
 - 26.6.2 Y-Scaling output lines

15

20

25

- In order to support scaling in the Y direction the following modifications to the PEC1 TE are suggested to the Tag Data Interface, Tag Format Structure Interface and TE Top Level:
 - for Tag Data Interface: program the configuration registers of Table , firstTagLineHeight and tagMaxLine with true value i.e. not multiplied up by the scale factor YScale. Within the Tag Data interface there are two counters, countx and county that have a direct bearing on the rawTagDataAddr generation. countx decrements as tags are read from DRAM. It is reset to NumTags[RtdTagSense] at start of each line of tags. county is decremented as each line of tags is completely read from DRAM i.e. countx = 0. Scaling may be performed by counting the number of times countx reaches zero and only decrementing county when this number reaches YScale. This will cause the TagData Interface to read each line of tag data NumTags[RtdTagSense] * YScale times.
 - for Tag Format Structure Interface: The implication of Y-scaling for the TFS is that each
 Tag Line Structure is used YScale times. This may be accomplished in either of two ways:
 - For each Tag Line Structure read it once from DRAM and reuse YScale times. This
 involves gating the control of TFS buffer flipping with YScale. Because of the way in which
 this advTfsLine and advTagLine related functionality is coded in the PEC1 TFS this solution
 is judged to be error-prone.
 - Fetch each TagLineStructure *YScale* times. This solution involves controlling the activity of *currTfsAddr* with *YScale*.
- In SoPEC the TFS must supply five addresses to the DIU to read each individual Tag Line Structure. The DIU returns 4*64-bit words for each of the 5 accesses. This is different from the behaviour in PEC1, where one address is given and 17 data-words were returned by the DIU.
- Since the behaviour of the *currTfsAddr* must be changed to meet the requirements of the SoPEC DIU it makes sense to include the Y-Scaling into this change i.e. a count of the number of completed sets of 5 accesses to the DIU is compared to YScale. Only when this count equals YScale can *currTfsAddr* be loaded with the base address of the next lines Tag Line Structure in DRAM, otherwise it is re-loaded with the base address of the current lines Tag Line Structure in DRAM.

• For Top Level: The Top Level of the TE has a counter, *LinePos*, which is used to count the number of completed output lines when in a tag gap or in a line of tags. At the start (i.e. top-left hand dot-pair) of a gap or tag *LinePos* is loaded with either *TagGapLine* or *TagMaxLine*. The value of *LinePos* is decremented at last dot-pair in line. Y-Scaling may be accomplished by gating the decrement of *LinePos* based on *YScale* value

26.6.3 TE Physical Hierarchy

5

10

15

Figure 188 above illustrates the structural hierarchy of the TE. The top level contains the Tag Data Interface (TDI), Tag Format Structure (TFS), and an FSM to control the generation of dot pairs along with a clocked process to carry out the PCU read/write decoding. There is also some additional logic for muxing the output data and generating other control signals.

At the highest level, the TE state machine processes the output lines of a page one line at a time, with the starting position either in an inter-tag gap or in a tag (a SoPEC may be only printing part of a tag due to multiple SoPECs printing a single line).

If the current position is within an inter-tag gap, an output of 0 is generated. If the current position is within a tag, the tag format structure is used to determine the value of the output dot, using the appropriate encoded data bit from the fixed or variable data buffers as necessary. The TE then advances along the line of dots, moving through tags and inter-tag gaps according to the tag placement parameters.

26.6.4 IO Definitions

20 Table 175. TE Port List

Port Name	Pins	I/O	Description
Clocks and Resets		<u> </u>	
Pclk	1	ln	SoPEC Functional clock.
prst_n	1	ln	Global reset signal.
Bandstore Signals			
cdu_endofbandstore[21:5]	17	ln	Address of the end of the current band of data.
			256-bit word aligned DRAM address.
cdu_startofbandstore[21:5]	17	In	Address of the start of the current band of data.
		1	256-bit word aligned DRAM address.
te_finishedband	1	Out	TE finished band signal to PCU and ICU.
PCU Interface data and con	trol sign	als	
pcu_addr[8:2]	7	In	PCU address bus. 7 bits are required to decode
			the address space for this block.
pcu_dataout[31:0]	32	In	Shared write data bus from the PCU.
te_pcu_datain[31:0]	32	Out	Read data bus from the TE to the PCU.
pcu_rwn	1	ln	Common read/not-write signal from the PCU.
pcu_te_sel	1	in	Block select from the PCU. When pcu_te_sel is
			high both <i>pcu_addr</i> and <i>pcu_dataout</i> are valid.

te_pcu_rdy	1	Out	Ready signal to the PCU. When te_pcu_rdy is
_, _ ,			high it indicates the last cycle of the access. For a
			write cycle this means pcu_dataout has been
			registered by the block and for a read cycle this
	=		means the data on te_pcu_datain is valid.
TD (raw Tag Data) DIU Rea	d Interfa	l ace siq	
td_diu_rreq	11	Out	TD requests DRAM read. A read request must be
			accompanied by a valid read address.
td_diu_radr[21:5]	17	Out	TD read address to DIU.
			17 bits wide (256-bit aligned word).
diu_td_rack	1	In	Acknowledge from DIU that TD read request has
			been accepted and new read address can be
			placed on <i>te_diu_radr</i> .
diu_data[63:0]	64	ln	Data from DIU to TE.
	ľ		First 64-bits are bits 63:0 of 256 bit word;
			Second 64-bits are bits 127:64 of 256 bit word;
	1		Third 64-bits are bits 191:128 of 256 bit word;
			Fourth 64-bits are bits 255:192 of 256 bit word.
diu_td_rvalid	1	ln	Signal from DIU telling TD that valid read data is
		:	on the <i>diu_data</i> bus.
TFS (Tag Format Structure) DIU Re	ead Inte	erface signals
tfs_diu_rreq	1	Out	TFS requests DRAM read. A read request must
			be accompanied by a valid read address.
tfs_diu_radr[21:5]	17	Out	TFS Read address to DIU
			17 bits wide (256-bit aligned word).
diu_tfs_rack	1	ln	Acknowledge from DIU that TFS read request has
			been accepted and new read address can be
			placed on <i>tfs_diu_radr</i> .
diu_data[63:0]	64	In	Data from DIU to TE.
			First 64-bits are bits 63:0 of 256 bit word;
			Second 64-bits are bits 127:64 of 256 bit word;
			Third 64-bits are bits 191:128 of 256 bit word;
			Fourth 64-bits are bits 255:192 of 256 bit word.
diu_tfs_rvalid	1	ln	Signal from DIU telling TFS that valid read data is
			on the <i>diu_data</i> bus.
TFU Interface data and cor	ntrol sign	als	
tfu_te_oktowrite	1	ln	Ready signal indicating TFU has space available
			and is ready to be written to. Also asserted from
			the point that the TFU has recieved its expected

			number of bytes for a line until the next te_tfu_wradvline
te_tfu_wdata[7:0]	8	Out	Write data for TFU.
te_tfu_wdatavalid	1	Out	Write data valid signal. This signal remains high whenever there is valid output data on te_tfu_wdata
te_tfu_wradvline	1	Out	Advance line signal strobed when the last byte in a line is placed on te_tfu_wdata

26.6.5 Configuration Registers

5

10

The configuration registers in the TE are programmed via the PCU interface.Refer to section 21.8.2 on page 321 for the description of the protocol and timing diagrams for reading and writing registers in the TE.Note that since addresses in SoPEC are byte aligned and the PCU only supports 32-bit register reads and writes the lower 2 bits of the PCU address bus are not required to decode the address space for the TE.Table 176 lists the configuration registers in the TE. Registers which address DRAM are 64-bit DRAM word aligned as this is the case for the PEC1 TE. SoPEC assumes a 256-bit DRAM word size. If the TE can be easily modified then the DRAM word addressing should be modified to 256-bit word aligned addressing. Otherwise, software should program these the 64-bit word aligned addresses on a 256-bit DRAM word boundary.

Table 176. TE Configuration Registers

Address	register name	#bits	value on reset	description
TE_base+				·
Control registers				
0x00	Reset	1	1	A write to this register causes
				a reset of the TE.
				This register can be read to
				indicate the reset state:
				0 - reset in progress
				1 - reset not in progress
0x04	Go	1	0	Writing 1 to this register starts
				the TE. Writing 0 to this
				register halts the TE.
				When Go is deasserted the
				state-machines go to their idle
				states but all counters and
				configuration registers keep
1				their values.
				When Go is asserted all
				counters are reset, but con-

	1	T	 	figuration registers keep their
				values (i.e. they don't get
				reset). NextBandEnable is
				cleared when Go is asserted.
				The TFU must be started
				before the TE is started.
				This register can be read to
				determine if the TE is running
				(1 = running, 0 = stopped).

_

The PCU accessible registers are divided amongst the TE top level and the TE sub-blocks. This is achieved by including write decoders in the sub-blocks as well as the top level, see Figure 189. In order to perform reads the sub-block registers are fed to the top level where the read decode is carried out on all the PCU accessible TE registers.

26.6.5.1 Starting the TE and restarting the TE between bands. The TE must be started after the TFU.

5

10

For the first band of data, users set up NextBandStartTagDataAdr, NextBandEndTagData and NextBandFirstTagLineHeight as well as other TE configuration registers. Users then set the TE's Go bit to start processing of the band. When the tag data for the band has finished being decoded, the te_finishedband interrupt will be sent to the PCU and ICU indicating that the memory associated with the first band is now free. Processing can now start on the next band of tag data.

In order to process the next band NextBandStartTagDataAdr, NextBandEndTagData and NextBandFirstTagLineHeight need to be updated before writing a 1 to NextBandEnable. There are 4 mechanisms for restarting the TE between bands:

- a. te_finishedband causes an interrupt to the CPU. The TE will have set its DoneBand bit. The CPU reprograms the NextBandStartTagDataAdr, NextBandEndTagData and NextBandFirstTagLineHeight registers, and sets NextBandEnable to restart the TE.
- b. The CPU programs the TE's NextBandStartTagDataAdr, NextBandEndTagData and NextBandFirstTagLineHeight registers and sets the NextBandEnable flag before the end of the current band. At the end of the current band the TE sets DoneBand. As NextBandEnable is already 1, the TE starts processing the next band immediately.
- c. The PCU is programmed so that te_finishedband triggers the PCU to execute commands from DRAM to reprogram the NextBandStartTagDataAdr, NextBandEndTagData and Next-BandFirstTagLineHeight registers and set the NextBandEnable bit to start the TE processing the next band. The advantage of this scheme is that the CPU could process band headers in advance and store the band commands in DRAM ready for execution.
- d. This is a combination of b and c above. The PCU (rather than the CPU in b) programs the TE's NextBandStartTagDataAdr, NextBandEndTagData and NextBandFirstTagLineHeight registers and sets the NextBandEnable bit before the end of the current band. At the end of the current band the TE sets DoneBand and pulses te_finishedband. As NextBandEnable is already 1, the TE starts processing the next band immediately. Simultaneously, te_finishedband triggers the PCU to fetch commands from DRAM. The TE will have restarted by the time the PCU has fetched commands from DRAM. The PCU commands program the TE next band shadow registers and sets the NextBandEnable bit.

After the first tag on the page, all bands have their first tag start at the top i.e.

25 NextBandFirstTagLineHeight = TagMaxLine. Therefore the same value of NextBandFirstTagLineHeight will normally be used for all bands. Certainly, NextBandFirstTagLineHeight should not need to change after the second time it is programmed. 26.6.6 TE Top Level FSM

The following diagram illustrates the states in the FSM.

5

10

15

20

- At the highest level, the TE state machine steps through the output lines of a page one line at a time, with the starting position either in an inter-tag gap (signal dotsintag = 0) or in a tag (signals tfsvalid and tdvalid and lineintag = 1) (a SoPEC may be only printing part of a tag due to multiple SoPECs printing a single line).
- If the current position is within an inter-tag gap, an output of 0 is generated. If the current position is within a tag, the tag format structure is used to determine the value of the output dot, using the appropriate encoded data bit from the fixed or variable data buffers as necessary. The TE then advances along the line of dots, moving through tags and inter-tag gaps according to the tag placement parameters.

Table 177 highlights the signals used within the FSM.

40 Table 177. Signals used within TE top level FSM

Signal Name	Function
pclk	Sync clock used to register all data within the FSM
prst_n, te_reset	Reset signals
advtagline	1 cycles pulse indicating to TDI and TFS sub-blocks to move onto the next line of Tag data
currdotlineadr[13:0]	Address counter starting 2 pclk ahead of currtagplaneadr to generate the correct dotpair for the current line
dotpos	Counter to identify how many dotpairs wide the tag/gap is
dotsintag	Signal identifying whether the dotpair are in a tag(1)/gap(0)
lineintag_temp	Identical to lineintag but generated 1 pclk earlier
linepos_shadow	Shadow register for linepos due to linepos being written to by 2 different processes
talaltsense	Flag which alternates between tag/gap lines
te_state	FSM state variable
teplanebuf	6-bit shift register used to format dotpairs into a byte for the TFU
wradvline	Advance line signal strobed when the last byte in a line is placed on te_tfu_wdata

Due to the 2 system clock delay in the TFS (both Table A and Table B outputs are registered) the TE FSM is working 2 system clock cycles AHEAD of the logic generating the write data for the TFU. As a result the following control signals had to be single/double registered on the system clock.

The tag_dot_line state can be broken down into 3 different stages.

5

10

15

Stage1:- The state tag_dot_line is entered due to the go signal becoming active. This state controls the writing of dotbytes to the TFU. As long as the tag line buffer address is not equal to the dotpairsperline register value and tfu_te_oktowrite is active, and there is valid TFS and TD available or taggaps, dotpairs are buffered into bytes and written to the TFU. The tag line buffer address is used internally but not supplied to the TFU since the TFU is a FIFO rather than the line store used in PEC1.

While generating the dotline of a tag/gap line (*lineintag* flag = 1) the dot position counter *dotpos* is decremented/reloaded (with tagmaxdotpairs or taggapdot) as the TE moves between tags/gaps. The *dotsintag* flag is toggled between tags/gaps (0 for a gap, 1 for a tag). This pattern continues until the end of a dotline approaches (*currdotlineadr* == *dotpairsperline*).

- 2 system clock cycles before the end of the dotline the *lineintag* and *tagaltsense* signals must be prepared for the next dotline be it in a tag/gap dotline or a purely gap dotlin⁻.
- Stage2:- At this point the end of a dot line is reached so it is time to decrement the *linepos* counter if still in a tag/gap row or reload the *linepos* register, *dotpos* counter and reprogram the *dotsintag* flag if going onto another tag/gap or pure gap row. Any signal with the _temp extension means this register is updated a cycle early in order for the real register to get its correct value while

switching between dot lines and tag rows when *dotpos* and *linepos* counters reach zero i.e when *dotpos* = 0 the end of a tag/gap has been reached, when *linepos* = 0 the end of a tag row is reached. This stage uses the signals *lineintag_temp* and *tagaltsense* which were generated one *system clock* cycle earlier in Stage 1.

5 Stage3:- This stage implements the writing of dotpairs to the correct part of the 6-bit shift register based on the LSBs of currtagplaneadr and also implements the counter for the currtagplaneadr. The currtagplaneadr is reset on reaching currtagplaneadr = (dotpairsperline - 1). All the qualifier signals e.g dotsintag for this stage are delayed by 2 system clock cycles i.e. the currtagplaneadr (which is the internal write address not needed by the TFU) cannot be incremented until the dotpairs are available which is always 2 system clock cycles later than when currdotlineadr is incremented.

The wradvline and advtagline pulses are generated using the same logic (currently separated in the PEC1 Tag Encoder VHDL for clarity). Both of these pulses used to update further registers hence the reason they do not use the delayed by 2 system clock cycle qualifiers.

15 26.6.7 Combinational Logic

25

30

35

The TDI is responsible for providing the information data for a tag while the TFSI is responsible for deciding whether a particular dot on the tag should be printed as background pattern or tag information. Every dot within a tag's boundary is either an information dot or part of the background pattern.

The resulting lines of dots are stored in the TFU.

The TFSI reads one Tag Line Structure (TLS) from the DIU for every dot line of tags. Depending on the current printing position within the tag (indicated by the signal *tagdotnum*), the TFS interface outputs dot information for two dots and if necessary the corresponding read addresses for encoded tag data. The read address are supplied to the TDI which outputs the corresponding data values.

These data values (tdi_etd0 and tdi_etd1) are then combined with the dot information (tfsi_ta_dot0 and tfsi_ta_dot1) to produce the dot values that will actually be printed on the page (dots), see Figure 192.

The signal *lastdotintag* is generated by checking that the dots are in a tag (*dotsintag* = 1) and that the dotposition counter dotpos is equal to zero. It is also used by the TFS to load the index address register with zeros at the end of a tag as this is always the starting index when going from one tag to the next. *lastdotintag* is gated with *advtagline* in the TFSi (Table C) where *adv_tfs_line* pulse is used to update the Table C address reg for the new tag line - this is because *lastdotintag* occurs a cycle earlier than *adv_tfs_line* which would result in the wrong Table C value for the last dotpair. *lastdotintag* is also used in the TDi FSM (etd_switch state) to pulse the *etd_advtag* signal hence switching buffers in the ETDi for the next tag.

The signal *lastdotintag1* is identical to *lastdotintag* except it is combinatorially generated (1 cycle earlier than *lastdotintag*, except at the end of a *tagline*). *lastdotintag1* signal is only used in the TDi to reset the *tdvalid* signal on the cycle when *dotpos* = 0. Note the UNSIGNED(*currdotlineadr*) =

UNSIGNED(dotpairsperline) - 1 not UNSIGNED(currdotlineadr) = UNSIGNED(dotpairsperline) - 2 as in the lastdotintag_gen process as this is an combinatorial process.

The dotposvalid signal is created based on being in a tag line (lineintag1 = 1), dots being in a tag (dotsintag1 = 1), having a valid tag format structure available (tfsvalid1 = 1) and having encoded tag data available (tdvalid1 = 1). Note that each of the qualifier signals are delayed by 1 pclk cycle due to the registering of Table A output data into Table C where dotposvalid is used. The dotposvalid signal is used as an enable to load the Table C address register with the next index into Table B which in turn provides the 2 addresses to make 2 dots available.

The signal *te_tfu_wdatavalid* can only be active if in a taggap or if valid tag data is available (*tdvalid2* and *tfsvalid2*) and the *currtagpplaneadr*(1:0) equal 11 i.e. a byte of data has been generated by combining four dotpairs.

The signal *tagdotnum* tells the TFS how many dotpairs remain in a tag/gap. It is calculated by subtracting the value in the *dotpos* counter from the value programmed in the *tagmaxdotpairs* register.

26.7.2 Introduction

The tag data interface is responsible for obtaining the raw tag data and encoding it as required by the tag encoder. The smallest typical tag placement is $2mm \times 2mm$, which means a tag is at least 126 1600 dpi dots wide.

- In PEC1, in order to keep up with the HCU which processes 2 dots per cycle, the tag data interface has been designed to be capable of encoding a tag in 63 cycles. This is actually accomplished in approximately 52 cycles within PEC1. For SoPEC the TE need only produce one dot per cycle; it should be able to produce tags in no more than twice the time taken by the PEC1 TE. Moreover, any change in implementation from two dots to one dot per cycle should not lose the 63/52 cycle performance edge attained in the PEC1 TE.
 - As shown in Figure 198, the tag data interface contains a raw tag data interface FSM that fetches tag data from DRAM, two symbol-at-a-time GF(2⁴) Reed-Solomon encoders, an encoded data interface and a state machine for controlling the encoding process. It also contains a *tagData* register that needs to be set up to hold the fixed tag data for the page.
- The type of encoding used depends on the registers *TE_encodefixed*, *TE_dataredun* and *TE_decode2den* the options being,

- (15,5) RS coding, where every 5 input symbols are used to produce 15 output symbols, so the output is 3 times the size of the input. This can be performed on fixed and variable tag data.
- (15,7) RS coding, where every 7 input symbols are used to produce 15 output symbols, so for the same number of input symbols, the output is not as large as the (15,5) code (for more details see section 26.7.6 on page 435). This can be performed on fixed and variable tag data.
 - 2D decoding, where each 2 input bits are used to produce 4 output bits. This can be performed on fixed and variable tag data.
- no coding, where the data is simply passed into the Encoded Data Interface. This can be performed on fixed data only.

Each tag is made up of fixed tag data (i.e. this data is the same for each tag on the page) and variable tag data (i.e. different for each tag on the page).

Fixed tag data is either stored in DRAM as 120-bits when it is already coded (or no coding is required), 40-bits when (15,5) coding is required or 56-bits when (15,7) coding is required. Once the fixed tag data is coded it is 120-bits long. It is then stored in the Encoded Tag Data Interface. The variable tag data is stored in the DRAM in uncoded form. When (15,5) coding is required, the 120-bits stored in DRAM are encoded into 360-bits. When (15,7) coding is required, the 112-bits stored in DRAM are encoded into 240-bits. When 2D decoding is required the 120-bits stored in DRAM are converted into 240-bits. In each case the encoded bits are stored in the Encoded Tag.

DRAM are converted into 240-bits. In each case the encoded bits are stored in the Encoded Tag

Data Interface.

The encoded fixed and variable tag data are eventually used to print the tag.

The fixed tag data is loaded in once from the DRAM at the start of a page. It is encoded as necessary and is then stored in one of the 8x15-bits registers/RAMs in the Encoded Tag Data Interface. This data remains unchanged in the registers/RAMs until the next page is ready to be processed.

The 120-bits of unencoded variable tag data for each tag is stored in four 32-bit words. The TE rereads the variable tag data, for a particular tag from DRAM, every time it produces that tag. The variable tag data FIFO which reads from DRAM has enough space to store 4 tags.

30 26.7.2.1 Bandstore wrapping

25

35

Both TD and TFS storage in DRAM can wrap around the bandstore area. The bounds of the band store are described by inputs from the CDU shown in Table . The TD and TFS DRAM interfaces therefore support bandstore wrapping. If the TD or TFS DRAM interface increments an address it is checked to see if it matches the end of bandstore address. If so, then the address is mapped to the start of the bandstore.

26.7.3 Data Flow

An overview of the dataflow through the TDI can be seen in Figure 198 below.

The TD interface consists of the following main sections:

- the Raw Tag Data Interface fetches tag data from DRAM;
- 40 the tag data register;

- 2 Reed Solomon encoders each encodes one 4-bit symbol at a time;
- the Encoded Tag Data Interface supplies encoded tag data for output;
- Two 2D decoders.

5

10

25

30

35

40

The main performance specification for PEC1 is that the TE must be able to output data at a continuous rate of 2 dots per cycle.

26.7.4 Raw tag data interface

The raw tag data interface (RTDI) provides a simple means of accessing raw tag data in DRAM. The RTDI passes tag data into a FIFO where it can be subsequently read as required. The 64-bit output from the FIFO can be read directly, with the value of the *wr_rd_counter* being used to set/reset as the enable signal (*rtdAvail*). The FIFO is clocked out with receipt of an *rtdRd* signal from the TS FSM.

Figure 199 shows a block diagram of the raw tag data interface.

26.7.4.1 RTDI FSM

The RTDI state machine is responsible for keeping the raw tag FIFO full. The state machine reads
the line of tag data once for each printline that uses the tag. This means a given line of tag data
will be read *TagHeight* times. Typically this will be 126 times or more, based on an approximately
2mm tag. Note that the first line of tag data may be read fewer times since the start of the page
may be within a tag. In addition odd and even rows of tags may contain different numbers of tags.
Section 26.6.5.1 outlines how to start the TE and restart it between bands. Users must set the

20 NextBandStartTagDataAdr, NextBandEndOfTagData, NextBandFirstTagLineHeight and numTags[0], numTags[1] registers before starting the TE by asserting Go.

To restart the tag encoder for second and subsequent bands of a page, the NextBandStartTagDataAdr, NextBandEndOfTagData and NextBandFirstTagLineHeight registers need to be updated (typically numTags[0] and numTags[1] will be the same if the previous band contains an even number of tag rows) and NextBandEnable set. See Section 26.6.5.1 for a full description of the four ways of reprogramming the TE between bands.

The tag data is read once for every printline containing tags. When maximally packed, a row of tags contains 163 tags (see Table n page 465 on page 408).

The RTDI State Flow diagram is shown in Figure 200. An explanation of the states follows: idle state:- Stay in the idle state if there is no variable data present. If there is variable data present and there are at least 4 spaces left in the FIFO then request a burst of 2 tags from the DRAM (1 * 256bits). Counter countx is assigned the number of tags in a even/odd line which depends on the value of register rtdtagsense. Down-counter county is assigned the number of dot lines high a tag will be (min 126). Initially it must be set the firsttaglineheight value as the TE may be between pages (i.e. a partial tag). For normal tag generation county will take the value of tagmaxline register.

diu_access:- The diu_access state will generate a request to the DRAM if there are at least 4 spaces in the FIFO. This is indicated by the counter wr_rd_counter which is incremented/decremented on writes/reads of the FIFO. As long as wr_rd_counter is less than 4 (FIFO is 8 high) there must be 4 locations free. A control signal called td_diu_radrvalid is

generated for the duration of the DRAM burst access. Addresses are sent in bursts of 1. The counter *burst_count* controls this signal, (will involve modification to existing TE code.)

If there is an odd number of tags in line then the last DRAM read will contain a tag in the first 128 bits and padding in the final 128 bits.

5 fifo_load:- This state controls the addressing to the DRAM. Counters countx and county are used to monitor whether the TE is processing a line of dots within a row of tags. When countx is zero it means all tag dots for this row are complete. When county is zero it means the TE is on the last line of dots (prior to Y scaling) for this row of tags. When a row of tags is complete the sense of rtdtagsense is inverted (odd/ even). The rawtagdataadr is compared to the te endoftagdata 10 address. If rawtagdataadr = endoftagdata the doneband signal is set, the finishedband signal is pulsed, and the FSM enters the rtd_stall state until the doneband signal is reset to zero by the PCU by which time the rawtagdata, endoftagedata and firsttaglineheight registers are setup with new values to restart the TE. This state is used to count the 64-bit reads from the DIU. Each time diu_td_rvalid is high rtd_data_count is incremented by 1. The compare of rtd_data_count = 15 rtd_num is necessary to find out when either all 4*64-bit data has been received or n*64-bit data (depending on a match of rawtagdataadr = endoftagdata in the middle of a set of 4*64-bit values being returned by the DIU.

rtd_stall:- This state waits for the the doneband signal to be reset (see page 426 for a description of how this occurs). Once reset the FSM returns to the idle state. This states also performs the same count on the diu_data read as above in the case where diu_td_rvalid has not gone high by the time the addressing is complete and the end of band data has been reached i.e. rawtagdataadr = endoftagdata

26.7.5 TDI state machine

20

25

30

40

The tag data state machine has two processing phases. The first processing phase is to encode the fixed tag data stored in the 128-bit (2×64 -bit) tag data register. The second is to encode tag data as it is required by the tag encoder.

When the Tag Encoder is started up, the fixed tag data is already preloaded in the 128 bit tag data record. If *encodeFixed* is set, then the 2 codewords stored in the lower bits of the tag data record need to be encoded: 40 bits if *dataRedun* = 0, and 56 bits if *dataRedun* = 1. If *encodeFixed* is clear, then the lower 120 bits of the tag data record must be passed to the encoded tag data interface without being encoded.

When *encodeFixed* is set, the symbols derived from codeword 0 are written to codeword 6 and the symbols derived from codeword 1 are written to codeword 7. The data symbols are stored first and then the remaining redundancy symbols are stored afterwards, for a total of 15 symbols.

Thus, when *dataRedun* = 0, the 5 symbols derived from bits 0-19 are written to symbols 0-4, and the redundancy symbols are written to symbols 5-14. When *dataRedun* = 1, the 7 symbols derived from bits 0-27 are written to symbols 0-6, and the redundancy symbols are written to symbols 7-14.

When *encodeFixed* is clear, the 120 bits of fixed data is copied directly to codewords 6 and 7. The TDI State Flow diagram is shown in Figure 202. An explanation of the states follows.

idle:- In the idle state wait for the tag encoder go signal - top_go = 1. The first task is to either store or encode the Fixed data. Once the Fixed data is stored or encoded/stored the donefixed flag is set. If there is no variable data the FSM returns to the idle state hence the reason to check the donefixed flag before advancing i.e. only store/encode the fixed data once.

fixed_data:- In the fixed_data state the FSM must decode whether to directly store the fixed data in the ETDi or if the fixed data needs to be either (15:5) (40-bits) or (15:7) (56-bits) RS encoded or 2D decoded. The values stored in registers encodefixed and dataredun and decode2den determine what the next state should be.

bypass_to_etdi:- The bypass_to_etdi takes 120-bits of fixed data(pre-encoded) from the tag_data(127:0) register and stores it in the 15*8 (by 2 for simultaneous reads) buffers. The data is passed from the tag_data register through 3 levels of muxing (level1, level2, level3) where it enters the RS0/RS1 encoders (which are now in a straight through mode (i.e. control_5 and control_7 are zero hence the data passes straight from the input to the output). The MSBs of the etd_wr_adr must be high to store this data as codewords 6,7.

etd_buf_switch:- This state is used to set the tdvalid signal and pulse the etd_adv_tag signal which in turn is used to switch the read write sense of the ETDi buffers (wrsb0). The firsttime signal is used to identify the first time a tag is encoded. If zero it means read the tag data from the RTDi FIFO and encode. Once encoded and stored the FSM returns to this state where it evaluates the sense of tdvalid. First time around it will be zero so this sets tdvalid and returns to the readtagdata state to fill the 2nd ETDi buffer. After this the FSM returns to this state and waits for the lastdotintag signal to arrive. In between tags when the lastdotingtag signal is received the etd_adv_tag is pulsed and the FSM goes to the readtagdata state. However if the lastdotintag signal arrives at the end of a line there is an extra 1 cycle delay introduced in generating the etd_adv_tag pulse (via etd_adv_tag_endofline) due to the pipelining in the TFS. This allows all the previous tag to be read from the correct buffer and seamless transfer to the other buffer for the

next line.

30

35

40

readtagdata:- The readtagdata state waits to receive a rtdavail signal from the raw tag data interface which indicates there is raw tag data available. The tag_data register is 128-bits so it takes 2 pulses of the rtdrd signal to get the 2*64-bits into the tag_data register. If the rtdavail signal is set rtdrd is pulsed for 1 cycle and the FSM steps onto the loadtagdata state. Initially the flag first64bits will be zero. The 64-bits of rtd are assigned to the tag_data[63:0] and the flag first64bits is set to indicate the first raw tag data read is complete. The FSM then steps back to the read_tagdata state where it generates the second rtdrd pulse. The FSM then steps onto the loadtagdata state for where the second 64-bits of rawtag data are assigned to tag_data[128:64]. loadtagdata:- The loadtagdata state writes the raw tag data into the tag_data register from the RTDi FIFO. The first64bits flag is reset to zero as the tag_data register now contains 120/112 bit

RTDi FIFO. The *first64bits* flag is reset to zero as the *tag_data* register now contains 120/112 bits of variable data. A decode of whether to (15:5) or (15:7) RS encode or 2D decode this data decides the next state.

rs_15_5:- The rs_15_5 (Reed Solomon (15:5) mode) state either encodes 40-bit Fixed data or 120-bit Variable data and provides the encoded tag data write address and write enable

(etd_wr_adr and etdwe respectively). Once the fixed tag data is encoded the donefixed flag is set as this only needs to be done once per page. The variabledatapresent register is then polled to see if there is variable data in the tags. If there is variable data present then this data must be read from the RTDi and loaded into the tag_data register. Else the tdvalid flag must be set and

5 FSM returns to the idle state. control_5 is a control bit for the RS Encoder and controls feedforward and feedback muxes that enable (15:5) encoding.

The rs_15_5 state also generates the control signals for passing 120-bits of variable tag data to the RS encoder in 4-bit symbols per clock cycle. *rs_counter* is used both to control the level1_mux and act as the 15-cycle counter of the RS Encoder. This logic cycles for a total of 3*15 cycles to encode the 120-bits.

rs_15_7:- The rs_15_7 state is similar to the rs_15_5 state except the level1_mux has to select 7 4-bit symbols instead of 5.

decode_2d_15_5, decode_2d_15_7:- The decode_2d states provides the control signals for passing the 120-bit variable data to the 2D decoder. The 2 lsbs are decoded to create 4 bits. The

4 bits from each decoder are combined and stored in the ETDi. Next the 2 MSBs are decoded to create 4 bits. Again the 4 bits from each decoder are combined and stored in the ETDi.

As can be seen from Figure n page488 on page **Error! Bookmark not defined.** there are 3 stages of muxing between the Tag Data register and the RS encoders or 2D decoders. Levels 1-2 are controlled by *level1_mux* and *level2_mux* which are generated within the TDi FSM as is the

write address to the ETDi buffers (etd_wr_adr)

Figures 203 through 208 illustrate the mappings used to store the encoded fixed and variable tag data in the ETDI buffers.

- 26.7.6 Reed Solomon (RS) Encoder
- 26.7.7 Introduction

10

15

A Reed Solomon code is a non binary, block code. If a symbol consists of m bits then there are $q = 2^m$ possible symbols defining the code alphabet. In the TE, m = 4 so the number of possible symbols is q = 16.

An (n,k) RS code is a block code with k information symbols and n code-word symbols. RS codes have the property that the code word n is limited to at most q+1 symbols in length.

In the case of the TE, both (15,5) and (15,7) RS codes can be used. This means that up to 5 and 4 symbols respectively can be corrected.

Only one type of RS coder is used at any particular time. The RS coder to be used is determined by the registers *TE_dataredun* and *TE_decode2den*:

- TE_dataredun = 0 and TE_decode2den = 0, then use the (15,5) RS coder
- TE_dataredun = 1 and TE_decode2den = 0, then use the (15,7) RS coder

For a (15,k) RS code with m = 4, k 4-bit information symbols applied to the coder produce 15 4-bit codeword symbols at the output. In the TE, the code is systematic so the first k codeword symbols are the same the as the k input information symbols.

A simple block diagram can be seen in.

40 26.7.8 I/O Specification

A I/O diagram of the RS encoder can be seen in.

26.7.9 Proposed implementation

In the case of the TE, (15,5) and (15,7) codes are to be used with 4-bits per symbol.

The primitive polynomial is $p(x) = x^4 + x + 1$

5 In the case of the (15,5) code, this gives a generator polynomial of

$$g(x) = (x+a)(x+a^2)(x+a^3)(x+a^4)(x+a^5)(x+a^6)(x+a^7)(x+a^8)(x+a^9)(x+a^{10})$$

$$g(x) = x^{10} + a^2x^9 + a^3x^8 + a^9x^7 + a^6x^6 + a^{14}x^5 + a^2x^4 + ax^3 + a^6x^2 + ax + a^2x^4 + ax^3 + a^6x^2 + ax + a^2x^4 + ax^$$

a¹⁰

$$g(x) = x^{10} + g_9 x^9 + g_8 x^8 + g_7 x^7 + g_6 x^6 + g_5 x^5 + g_4 x^4 + g_3 x^3 + g_2 x^2 + g_1 x$$

10 + g₀

In the case of the (15,7) code, this gives a generator polynomial of

$$h(x) = (x+a)(x+a^2)(x+a^3)(x+a^4)(x+a^5)(x+a^6)(x+a^7)(x+a^8)$$

$$h(x) = x^8 + a^{14}x^7 + a^2x^6 + a^4x^5 + a^2x^4 + a^{13}x^3 + a^5x^2 + a^{11}x + a^6$$

$$h(x) = x^8 + h_7x^7 + h_6x^6 + h_5x^5 + h_4x^4 + h_3x^3 + h_2x^2 + h_1x + h_0$$

The output code words are produced by dividing the generator polynomial into a polynomial made up from the input symbols.

This division is accomplished using the circuit shown in Figure 211.

The data in the circuit are Galois Field elements so addition and multiplication are performed using special circuitry. These are explained in the next sections.

The RS coder can operate either in (15,5) or (15,7) mode. The selection is made by the registers TE_dataredun and TE_decode2den.

When operating in (15,5) mode *control_7* is always zero and when operating in (15,7) mode *control_5* is always zero.

Firstly consider (15,5) mode i.e. TE_dataredun is set to zero.

25 For each new set of 5 input symbols, processing is as follows:

The 4-bits of the first symbol d_0 are fed to the input port $rs_data_in(3:0)$ and $control_5$ is set to 0. mux2 is set so as to use the output as feedback. $control_5$ is zero so mux4 selects the input (rs_data_in) as the output (rs_data_out) . Once the data has settled (<< 1 cycle), the shift registers are clocked. The next symbol d_1 is then applied to the input, and again after the data has settled the shift registers are clocked again. This is repeated for the next 3 symbols d_2 , d_3 and d_4 . As a result, the first 5 outputs are the same as the inputs. After 5 cycles, the shift registers now contain the next 10 required outputs. $control_5$ is set to 1 for the next 10 cycles so that zeros are fed back by mux2 and the shift register values are fed to the output by mux3 and mux4 by simply clocking the registers.

35 A timing diagram is shown below.

30

40

Secondly consider (15,7) mode i.e. TE_dataredun is set to one.

In this case processing is similar to above except that $control_7$ stays low while 7 symbols (d_0 , d_1 ... d_6) are fed in. As well as being fed back into the circuit, these symbols are fed to the output. After these 7 cycles, $control_7$ is set to 1 and the contents of the shift registers are fed to the output.

A timing diagram is shown below.

The enable signal can be used to start/reset the counter and the shift registers.

The RS encoders can be designed so that encoding starts on a rising *enable* edge. After 15 symbols have been output, the encoder stops until a rising *enable* edge is detected. As a result there will be a delay between each codeword.

Alternatively, once the enable goes high the shift registers are reset and encoding will proceed until it is told to stop. *rs_data_in* must be supplied at the correct time. Using this method, data can be continuously output at a rate of 1 symbol per cycle, even over a few codewords.

Alternatively, the RS encoder can request data as it requires.

- The performance criterion that must be met is that the following must be carried out within 63 cycles
 - load one tag's raw data into TE_tagdata
 - encode the raw tag data
 - store the encoded tag data in the Encoded Tag Data Interface
- In the case of the raw fixed tag data at the start of a page, there is no definite performance criterion except that it should be encoded and stored as fast as possible.

26.7.10 Galois Field elements and their representation

A Galois Field is a set of elements in which we can do addition, subtraction, multiplication and division without leaving the set.

The TE uses RS encoding over the Galois Field $GF(2^4)$. There are 2^4 elements in $GF(2^4)$ and they are generated using the primitive polynomial $p(x) = x^4 + x + 1$.

The 16 elements of GF(2⁴) can be represented in a number of different ways. Table 179 shows three possible representations - the power, polynomial and 4-tuple representation.

Table 179. GF(2⁴) representations

26.7.11 Multiplication of GF(24) elements

The multiplication of two field elements α^a and α^b is defined as

$$\alpha^{c} = \alpha^{a}.\alpha^{b} = \alpha^{(a+b)modulo 15}$$

Thus

5

$$\alpha^1.\alpha^2 = \alpha^3$$

$$\alpha^5.\alpha^{10} = \alpha^{15}$$

$$\alpha^6.\alpha^{12} = \alpha^3$$

So if we have the elements in exponential form, multiplication is simply a matter of modulo 15 addition.

If the elements are in polynomial/tuple form, the polynomials must be multiplied and reduced mod $x^4 + x + 1$.

Suppose we wish to multiply the two field elements in GF(2⁴):

$$\alpha^a = a_3 x^3 + a_2 x^2 + a_1 x^1 + a_0$$

$$\alpha^b = b_3 x^3 + b_2 x^2 + b_1 x^1 + b_0$$

15

where a_i, b_i are in the field (0,1) (i.e. modulo 2 arithmetic)

Multiplying these out and using $x^4 + x + 1 = 0$ we get:

$$\alpha^{a+b} = [(a_0b_3 + a_1b_2 + a_2b_1 + a_3b_0) + a_3b_3]x^3$$

$$+ [(a_0b_2 + a_1b_1 + a_2b_0) + a_3b_3 + (a_3b_2 + a_2b_3)]x^2$$

$$+ [(a_0b_1 + a_1b_0) + (a_3b_2 + a_2b_3) + (a_1b_3 + a_2b_2 + a_3b_1)]x$$

$$+ [(a_0b_0 + a_1b_3 + a_2b_2 + a_3b_1)]$$

$$\alpha^{a+b} = [a_0b_3 + a_1b_2 + a_2b_1 + a_3(b_0 + b_3)]x^3$$

$$+ [a_0b_2 + a_1b_1 + a_2(b_0 + b_3) + a_3(b_2 + b_3)]x^2$$

$$+ [a_0b_1 + a_1(b_0 + b_3) + a_2(b_2 + b_3) + a_3(b_1 + b_2)]x$$

25

20

If we wish to multiply an arbitrary field element by a fixed field element we get a more simple form. Suppose we wish to multiply α^b by α^3 .

 $+ [a_0b_0 + a_1b_3 + a_2b_2 + a_3b_1]$

In this case $\alpha^3 = x^3$ so (a0 a1 a2 a3) = (0 0 0 1). Substituting this into the above equation gives

$$\alpha^{c} = (b_0 + b_3)x^3 + (b_2 + b_3)x^2 + (b_1 + b_2)x + b_1$$

This can be implemented using simple XOR gates as shown in Figure 214

26.7.12 Addition of GF(24) elements

If the elements are in their polynomial/tuple form, polynomials are simply added.

Suppose we wish to add the two field elements in GF(24):

$$\alpha^{a} = a_{3}x^{3} + a_{2}x^{2} + a_{1}x + a_{0}$$

 $\alpha^{b} = b_{3}x^{3} + b_{2}x^{2} + b_{1}x + b_{0}$

where a_i, b_i are in the field (0,1) (i.e. modulo 2 arithmetic)

$$\alpha^{c} = \alpha^{a} + \alpha^{b} = (a_{3} + b_{3})x^{3} + (a_{2} + b_{2})x^{2} + (a_{1} + b_{1})x + (a_{0} + b_{0})$$

5 Again this can be implemented using simple XOR gates as shown in Figure 215

26.7.13 Reed Solomon Implementation

15

The designer can decide to create the relevant addition and multiplication circuits and instantiate them where necessary. Alternatively the feedback multiplications can be combined as follows. Consider the multiplication

10
$$\alpha^a.\alpha^b = \alpha^c$$
 or in terms of polynomials
$$(a_3x^3 + a_2x^2 + a_1x + a_0).(b_3x^3 + b_2x^2 + b_1x + b_0) = (c_3x^3 + c_2x^2 + c_1x + c_0)$$

If we substitute all of the possible field elements in for α^a and express α^c in terms of α^b , we get the table of results shown in Table 180.

Table 180. α^c multiplied by all field elements, expressed in terms of α^b

αa = a3x3 +	a2x2 + a1x + a0	c3x3 + c2x2 + c1x + c0

α^{10}	(1 1 1 0)	b ₀ +b ₂ +b ₃	b ₀ +b ₁ +b ₂	b ₀ +b ₁ +b ₂ +b ₃	b ₁ +b ₂ +b ₃
α^{11}	(0 1 1 1)	b ₁ +b ₂ +b ₃	b ₀ +b ₁	b ₀ +b ₁ +b ₂	b ₀ +b ₁ +b ₂
					+b ₃
α^{12}	(1 1 1 1)	b ₀ +b ₁ +b ₂ +b ₃	b ₀	b ₀ +b ₁	b ₀ +b ₁ +b ₂
α^{13}	(1 0 1 1)	b ₀ +b ₁ +b ₂	b ₃	b ₀	b₀+b₁
α^{14}	(1 0 0 1)	b ₀ +b ₁	b ₂	b ₃	b _o

the following signals are required:

- b₀, b₁, b₂, b₃
- (b_0+b_1) , (b_0+b_2) , (b_0+b_3) , (b_1+b_2) , (b_1+b_3) , (b_2+b_3) ,
- $(b_0+b_1+b_2)$, $(b_0+b_1+b_3)$, $(b_0+b_2+b_3)$, $(b_1+b_2+b_3)$,
- $(b_0+b_1+b_2+b_3)$

The implementation of the circuit can be seen in Figure . The main components are XOR gates, 4-bit shift registers and multiplexers.

The RS encoder has 4 input lines labelled 0,1,2 & 3 and 4 output lines labelled 0,1,2 & 3. This labelling corresponds to the subscripts of the polynomial/4-tuple representation. The mapping of 4-bit symbols from the TE_tagdata register into the RS is as follows:

- the LSB in the TE_tagdata is fed into line0
- the next most significant LSB is fed into line1
- the next most significant LSB is fed into line2
- the MSB is fed into line3

5

10

- The RS output mapping to the Encoded tag data interface is similiar. Two encoded symbols are stored in an 8-bit address. Within these 8 bits:
 - line0 is fed into the LSB (bit 0/4)
 - line1 is fed into the next most significant LSB (bit 1/5)
 - line2 is fed into the next most significant LSB (bit 2/6)
- line3 is fed into the MSB (bit 3/7)

267.14 2D Decoder

The 2D decoder is selected when TE_decode2den = 1. It operates on variable tag data only. its function is to convert 2-bits into 4-bits according to Table 181..

Table 181. Operation of 2D decoder

input	output
0 0	0001
0 1	0010
1 0	0100
1 1	1000

26.7.15 Encoded tag data interface

The encoded tag data interface contains an encoded fixed tag data store interface and an encoded variable tag data store interface, as shown in Figure 217.

The two reord units simply reorder the 9 input bits to map low-order codewords into the bit selection component of the address as shown in Table 182. Reordering of write addresses is not necessary since the addresses are already in the correct format.

Table 182. Reord unit

bit#	input		output	
	bit	interpretation	bit	interpretation
8	Α	select 1 of 8 codewords	Α	select 1 of 4 codeword
				tables
7	В		В	
6	С		D	select 1 of 15 symbols
5	D	select 1 of 15 symbols	E	
4	E		F	
3	F		G	
2	G		С	select 1 of 8 bits
1	Н	select 1 of 4 bits	Н	
0	I		1	

The encoded fixed data interface is a single 15×8 -bit RAM with 2 read ports and 1 write port. As it is only written to during page setup time (it is fixed for the duration of a page) there is no need for simultaneous read/write access. However the fixed data store must be capable of decoding two simultaneous reads in a single cycle. Figure 218 shows the implementation of the fixed data store.

The encoded variable tag data interface is a double buffered $3 \times 15 \times 8$ -bit RAM with 2 read ports and 1 write port. The double buffering allows one tag's data to be read (two reads in a single cycle) while the next tag's variable data is being stored. Write addressing is 6 bits: 2 bits of address for selecting 1 of 3, and 4 bits of address for selecting 1 of 15. Read addressing is the same with the addition of 3 more address bits for selecting 1 of 8.

Figure 219 shows the implementation of the encoded variable tag data store. Double buffering is implemented via two sub-buffers. Each time an *AdvTag* pulse is received, the sense of which sub-buffer is being read from or written to changes. This is accomplished by a 1-bit flag called *wrsb0*.

Although the initial state of *wrsb0* is irrelevant, it must invert upon receipt of an *AdvTag* pulse. The structure of each sub-buffer is shown in Figure 220.

26.8 TAG FORMAT STRUCTURE (TFS) INTERFACE

26.8.1 Introduction

5

10

The TFS specifies the contents of every dot position within a tags border i.e.:

- is the dot part of the background?
 - is the dot part of the data?

The TFS is broken up into Tag Line Structures (TLS) which specify the contents of every dot position in a particular line of a tag. Each TLS consists of three tables - A, B and C (see Figure 221).

For a given line of dots, all the tags on that line correspond to the same tag line structure.

Consequently, for a given line of output dots, a single tag line structure is required, and not the entire TFS. Double buffering allows the next tag line structure to be fetched from the TFS in DRAM while the existing tag line structure is used to render the current tag line.

The TFS interface is responsible for loading the appropriate line of the tag format structure as the tag encoder advances through the page. It is also responsible for producing table A and table B outputs for two consecutive dot positions in the current tag line.

- There is a TLS for every dot line of a tag.
- All tags that are on the same line have the exact same TLS.
 - A tag can be up to 384 dots wide, so each of these 384 dots must be specified in the TLS.
 - The TLS information is stored in DRAM and one TLS must be read into the TFS Interface for each line of dots that are outputted to the Tag Plane Line Buffers.
 - Each TLS is read from DRAM as 5 times 256-bit words with 214 padded bits in the last 256-bit DRAM read.

26.8.2 I/O Specification

10

Table 183. Tag Format Structure Interface Port List

signal name	signal type	description
Pclk	In	SoPEC system clock
prst_n	In	Active-low, synchronous reset in pclk domain
top_go	ln	Go signal from TE top level
DRAM		
diu_data[63:0]	ln	Data from DRAM
diu_tfs_rack	ln	Data acknowledge from DRAM
diu_tfs_rvalid	In	Data valid from DRAM
tfs_diu_rreq	Out	Read request to DRAM
tfs_diu_radr[21:5]	Out	Read address to DRAM
tag encoder top level		
top_advtagline	In	Pulsed after the last line of a row of tags
top_tagaltsense	ln	For even tag rows = 0 i.e. 0,2,4
		For odd tag rows = 1 i.e. 1,3,5
top_lastdotintag	In	Last dot in tag is currently being processed
top_dotposvalid	ln	Current dot position is a tag dot and its structure data
		and tag data is available
top_tagdotnum[7:0]	ln	Counts from zero up to TE_tagmaxdotpairs (min. =1,
		max. = 192)
tfsi_valid	Out	TLS tables A, B and C, ready for use
tfsi_ta_dot0[1:0]	Out	Even entry from Table A corresponding to
		top_tagdotnum
tfsi_ta_dot1[1:0]	Out	Odd entry from Table A corresponding to
		top_tagdotnum
tag encoder top lev	/el	•
(PCU read decoder)		

tfs_te_tfsstartadr[23:0]	Out	TFS tfsstartadr register
tfs_te_tfsendadr[23:0]	Out	TFS tfsendadr register
tfs_te_tfsfirstlineadr[23:0]	Out	TFS tfsfirstlineadr register
tfs_te_currtfsadr[23:0]	Out	TFS currtfsadr register
TDI		
tfsi_tdi_adr0[8:0]	Out	Read address for dot0 (even dot)
tfsi_tdi_adr1[8:0]	Out	Read address for dot1 (odd dot)

26.8.2.1 State machine

5

20

25

30

The state machine is responsible for generating control signals for the various TFS table units, and to load the appropriate line from the TFS. The states are explained below.

idle:- Wait for top_go to become active. Pulse adv_tfs_line for 1 cycle to reset tawradr and tbwradr registers. Pulsing adv_tfs_line will switch the read/write sense of Table B so switching Table A here as well to keep things the same i.e. wrta0 = NOT(wrta0).

diu_access:- In the diu_access state a request is sent to the DIU. Once an ack signal is received Table A write enable is asserted and the FSM moves to the t/s_load state.

t/s_load:- The DRAM access is a burst of 5 256-bit accesses, ultimately returned by the DIU as 5*(4*64bit) words. There will be 192 padded bits in the last 256-bit DRAM word. The first 12 64-bit words reads are for Table A, words 12 to 15 and some of 16 are for Table B while part of read 16 data is for Table C. The counter read_num is used to identify which data goes to which table. The table B data is stored temporarily in a 288-bit register until the tls_update state hence tbwe does not become active until read_num = 16).

- The DIU data goes directly into Table A (12 * 64).
 - The DIU data for Table B is loaded into a 288-bit register.
 - The DIU data goes directly into Table C.

tls_update:- The 288-bits in Table B need to written to a 32*9 buffer. The tls_update state takes care of this using the read_num counter.

tls_next:- This state checks the logic level of tfsvalid and switches the read/write senses of Table A (wrta0) and Table B a cycle later (using the adv_tfs_line pulse). The reason for switching Table A a cycle early is to make sure the top_level address via tagdotnum is pointing to the correct buffer. Keep in mind the top_level is working a cycle ahead of Table A and 2 cycles ahead of Table B.

If *tfsValid* is 1, the state machine waits until the *advTagLine* signal is received. When it is received, the state machine pulses *advTFSLine* (to switch read/write sense in tables A, B, C), and starts reading the next line of the TFS from *currTFSAdr*.

If tfsValid is 0, the state machine pulses advTFSLine (to switch read/write sense in tables A, B, C) and then jumps to the tls_tfsvalid_set state where the signal tfsValid is set to 1 (allowing the tag encoder to start, or to continue if it had been stalled). The state machine can then start reading the next line of the TFS from currTFSAdr.

tls_tfsvalid_next:- Simply sets the tfsvalid signal and returns the FSM to the diu_access state.

If an advTagLine signal is received before the next line of the TFS has been read in, tfsValid is cleared to 0 and processing continues as outlined above.

26.8.2.2 Bandstore wrapping

5

15

20

25

30

Both TD and TFS storage in DRAM can wrap around the bandstore area. The bounds of the band store are described by inputs from the CDU shown in Table . The TD and TFS DRAM interfaces therefore support bandstore wrapping. If the TD or TFS DRAM interface increments an address it is checked to see if it matches the end of bandstore address. If so, then the address is mapped to the start of the bandstore.

The TFS state flow diagram is shown in below.

10 26.8.3 Generating a tag from Tables A, B and C

The TFS contains an entry for each dot position within the tag's bounding box. Each entry specifies whether the dot is part of the constant background pattern or part of the tag's data component (both fixed and variable).

The TFS therefore has TagHeight x TagWidth entries, where TagHeight is the height of the tag in dot-lines and TagWidth is the width of the tag in dots. The TFS entries that specify a single dot-line of a tag are known as a Tag Line Structure.

The TFS contains a TLS for each of the 1600 dpi lines in the tag's bounding box. Each TLS contains three contiguous tables, known as tables A, B and C.

Table A contains 384 2-bit entries i.e. one entry for each dot in a single line of a tag up to the maximum width of a tag. The actual number of entries used should match the size of the bounding box for the tag in the dot dimension, but all 384 entries must be present.

Table B contains 32 9-bit data address that refer to (in order of appearance) the data dots present in the particular line. Again, all 32 entries must be present, even if fewer are used.

Table C contains two 5-bit pointers into table B and is followed by 22 unused bits. The total length of each TLS is therefore 34 32-bit words.

Each output dot value is generated as follows: Each entry in Table A consists of 2-bits - bit0 and bit1. These 2-bits are interpreted according to Table 184, Table 185 and Table 186.

Table 184. Interpretation of bit0 from entry in Table A

bit0	interpretation	
O	the output bit comes directly from bit1 (see Table).	
1	the output bit comes from a data bit. Bit1 is used in conjunction	
	Tag Line Structure Table B to determine which data bit will be output.	

Table 185. Interpretation of bit1 from entry in table A when bit0 = 0

bit 1	interpretation
0	output 0
1	output 1

Table 186. Interpretation of bit1 from entry in table A when bit0 = 1

bit 1	interpretation	
0	output data bit pointed to by current index into Table B.	
1	output data bit pointed to by current index into Table B, and adv	
	index by 1.	

If bit0 = 0 then the output dot for this entry is part of the constant background pattern. The dot value itself comes from bit1 i.e. if bit1 = 0 then the output is 0 and if bit1 = 1 then the output is 1. If bit0 = 1 then the output dot for this entry comes from the variable or fixed tag data. Bit1 is used in conjunction with Tables B and C to determine data bits to use.

To understand the interpretation of bit1 when bit0 = 1 we need to know what is stored in Table B. Table B contains the addresses of all the data bits that are used in the particular line of a tag in order of appearance. Therefore, up to 32 different data bits can appear in a line of a tag. The address of the first data dot in a tag will be given by the address stored in entry 0 of Table B. As we advance along the various data dots we will advance through the various Table B entries. Each Table B entry is 9-bits long and each points to a specific variable or fixed data bit for the tag. Each tag contains a maximum of 120 fixed and 360 variable data bits, for a total of 480 data bits. To aid address decoding, the addresses are based on the RS encoded tag data. Table lists the interpretation of the 9-bit addresses.

Table 187. Interpretation of 9-bit tag data address in Table B

5

10

15

20

bit pos	name	description
8	CodeWordSelect	Select 1 of 8 codewords.
		Codewords 0, 1, 2, 3, 4, 5 are variable data.
		Codewords 6, 7 are fixed data.
7		
6		
5	SymbolSelect	Select 1 of 15 symbols (1111 invalid)
4		
3		
2		
1	BitSelect	Select 1 of 4 bits from the selected symbols
0		

If the fixed data is supplied to the TE in an unencoded form, the symbols derived from codeword 0 of fixed data are written to codeword 6 and the symbols derived from fixed data codeword 1 are written to codeword 7. The data symbols are stored first and then the remaining redundancy symbols are stored afterwards, for a total of 15 symbols. Thus, when 5 data symbols are used, the 5 symbols derived from bits 0-19 are written to symbols 0-4, and the redundancy symbols are written to symbols 5-14. When 7 data symbols are used, the 7 symbols derived from bits 0-27 are written to symbols 0-6, and the redundancy symbols are written to symbols 7-14

However, if the fixed data is supplied to the TE in a pre-encoded form, the encoding could theoretically be anything. Consequently the 120 bits of fixed data is copied to codewords 6 and 7 as shown in Table 188.

Table 188. Mapping of fixed data to codeword/symbols when no redundancy encoding

	1
_	

10

15

30

input bits	output symbol	output
	range	codeword
0-19	0-4	6
20-39	0-4	7
40-59	5-9	6
60-79	5-9	7
80-99	10-14	6
100-119	10-14	7

It is important to note that the interpretation of bit1 from Table A (when bit0 = 1) is relative. A 5-bit index is used to cycle through the data address in Table B. Since the first tag on a particular line may or may not start at the first dot in the tag, an initial value for the index into Table B is needed. Subsequent tags on the same line will always start with an index of 0, and any partial tag at the end of a line will simply finish before the entire tag has been rendered. The initial index required due to the rendering of a partial tag at the start of a line is supplied by Table C. The initial index will be different for each TLS and there are two possible initial indexes since there are effectively two types of rows of tags in terms of initial offsets.

Table C provides the appropriate start index into Table B (2 5-bit indices). When rendering even rows of tags, entry 0 is used as the initial index into Table B, and when rendering odd rows of tags, entry 1 is used as the initial index into Table B. The second and subsequent tags start at the left most dots position within the tag, so can use an initial index of 0.

26.8.4 Architecture

A block diagram of the Tag Format Structure Interface can be seen in Figure 223.

20 26.8.4.1 Table A interface

The implementation of table A is two 16×64 -bit RAMs with a small amount of control logic, as shown in Figure 224. While one RAM is read from for the current line's table A data (4 bits representing 2 contiguous table A entries), the other RAM is being written to with the next line's table A data (64-bits at a time).

Note:- The Table A data to be printed (if each LSB = 0) must be passed to the top_level 2 cycles after the read of Table A due to the 2-stage pipelining in the TFS from registering Table A and Table B outputs hence this extra registering stage for the generation of ta_dot0_1cyclelater and ta_dot1_1cyclelater.

Each time an *AdvTFSLine* pulse is received, the sense of which RAM is being read from or written to changes. This is accomplished by a 1-bit flag called *wrta0*. Although the initial state of *wrta0* is irrelevant, it must invert upon receipt of an *AdvTFSLine* pulse. A 4-bit counter called *taWrAdr* keeps the write address for the 12 writes that occur after the start of each line (specified by the

AdvTFSLine control input). The tawe (table A write enable) input is set whenever the data in is to be written to table A. The taWrAdr address counter automatically increments with each write to table A. Address generation for tawe and taWrAdr is shown in Table 189.

26.8.4.2 Table C interface

A block diagram of the table C interface is shown below in Figure 226.

The address generator for table C contains a 5 bit address register adr that is set to a new address at the start of processing the tag (either of the two table C initial values based on tagAltSense at the start of the line, and 0 for subsequent tags on the same line). Each cycle two addresses into table B are generated based on the two 2-bit inputs (in0 and in1). As shown in Section 189, the output address tbRdAdr0 is always adr and tbRdAdr1 is one of adr and adr+1, and at the end of the cycle adr takes on one of adr, adr+1, and adr+2.

Table 189. AdrGen lookup table

input	s	outputs			
in0	in1	adr0Sel	adr1Sel	adrSel	
00	00	X ¹⁸	×	adr	
00	01	×	adr	adr	
00	10	×	×	adr	
00	11	×	adr	adr+1	
01	00	adr	×	adr	
01	01	adr	adr	adr	
01	10	adr	X	adr	
01	11	adr	adr	adr+1	
10	00	X	×	adr	
10	01	X	adr	adr	
10	10	X	×	adr	
10	11	×	adr	adr+1	
11	00	adr	X	adr+1	
11	01	adr	adr+1	adr+1	
11	10	adr	×	adr+1	
11	11	adr	adr+1	adr+2	

26.8.4.3 Table B interface

The table B interface implementation generates two encoded tag data addresses (*tfsi_adr0*, *tfsi_adr1*) based on two table B input addresses (*tbRdAdr0*, *tbRdAdr1*). A block diagram of table B can be seen in Figure 227.

¹⁸ X = don't care state.

Table B data is initially loaded into the 288-bit table B temporary register via the TFS FSM. Once all 288-bit entries have been loaded from DRAM, the data is written in 9-bit chunks to the 32*9 register arrays based on tbwradr.

Each time an *AdvTFSLine* pulse is received, the sense of which sub buffer is being read from or written to changes. This is accomplished by a 1-bit flag called *wrtb0*. Although the initial state of *wrtb0* is irrelevant, it must invert upon receipt of an *AdvTFSLine* pulse.

Note:- The output addresses from Table B are registered.

27 Tag FIFO Unit (TFU)

27.1 OVERVIEW

5

15

The Tag FIFO Unit (TFU) provides the means by which data is transferred between the Tag Encoder (TE) and the HCU. By abstracting the buffering mechanism and controls from both units, the interface is clean between the data user and the data generator.

The TFU is a simple FIFO interface to the HCU. The Tag Encoder will provide support for arbitrary Y integer scaling up to 1600 dpi. X integer scaling of the tag dot data is performed at the output of the FIFO in the TFU. There is feedback to the TE from the TFU to allow stalling of the TE during a line. The TE interfaces to the TFU with a data width of 8 bits. The TFU interfaces to the HCU with a data width of 1 bit.

The depth of the TFU FIFO is chosen as 16 bytes so that the FIFO can store a single 126 dot tag. 27.1.1 Interfaces between TE, TFU and HCU

20 27.1.1.1 TE-TFU Interface

The interface from the TE to the TFU comprises the following signals:

- te_tfu_wdata, 8-bit write data.
- te_tfu_wdatavalid, write data valid.
- te_tfu_wradvline, accompanies the last valid 8-bit write data in a line.
- 25 The interface from the TFU to TE comprises the following signal:
 - tfu_te_oktowrite, indicating to the TE that there is space available in the TFU FIFO.

The TE writes data to the TFU FIFO as long as the TFU's *tfu_te_oktowrite* output bit is set. The TE write will not occur unless data is accompanied by a data valid signal.

27.1.1.2 TFU-HCU Interface

- The interface from the TFU to the HCU comprises the following signals:
 - tfu hcu tdata, 1-bit data.
 - tfu_hcu_avail, data valid signal indicating that there is data available in the TFU FIFO.

The interface from HCU to TFU comprises the following signal:

hcu_tfu_ready, indicating to the TFU to supply the next dot.

35 27.1.1.2.1 X scaling

Tag data is replicated a scale factor (SF) number of times in the X direction to convert the final output to 1600 dpi. Unlike both the CFU and SFU, which support non-integer scaling, the scaling is integer only. Replication in the X direction is performed at the output of the TFU FIFO on a dot-by-dot basis.

To account for the case where there may be two SoPEC devices, each generating its own portion of a dot-line, the first dot in a line may not be replicated the total scale-factor number of times by an individual TFU. The dot will ultimately be scaled-up correctly with both devices doing part of the scaling, one on its lead-out and the other on its lead in.

Note two SoPEC TEs may be involved in producing the same byte of output tag data straddling the printhead boundary. The HCU of the left SoPEC will accept from its TE the correct amount of dots, ignoring any dots in the last byte that do not apply to its printhead. The TE of the right SoPEC will be programmed the correct number of dots into the tag and its output will be byte aligned with the left edge of the printhead.

10 27.2 DEFINITIONS OF I/O Table 190. TFU Port List

Port Name	Pins	1/0	Description
Clocks and Resets		l	
Pclk	1	In	SoPEC Functional clock.
Prst_n	1	In	Global reset signal.
PCU Interface data and control			
signals			
Pcu_adr[4:2]	2	ln	PCU address bus. Only 3 bits are
			required to decode the address space
			for this block.
Pcu_dataout[31:0]	32	In	Shared write data bus from the PCU.
Tfu_pcu_datain[31:0]	32	Out	Read data bus from the TFU to the
			PCU.
Pcu_rwn	1	ln	Common read/not-write signal from the
			PCU.
Pcu_tfu_sel	1	In	Block select from the PCU. When
			pcu_tfu_sel is high both pcu_adr and
			pcu_dataout are valid.
Tfu_pcu_rdy	1	Out	Ready signal to the PCU. When
			tfu_pcu_rdy is high it indicates the last
			cycle of the access. For a write cycle
	!		this means <i>pcu_dataout</i> has been
			registered by the block and for a read
			cycle this means the data on
			tfu_pcu_datain is valid.
TE Interface data and control		•	
signals			
Te_tfu_wdata[7:0]	8	ln	Write data for TFU FIFO.

Te_tfu_wdatavalid	1	In	Write data valid signal.
Te_tfu_wradvline	1	In	Advance line signal strobed when the last byte in a line is placed on te_tfu_wdata
tfu_te_oktowrite	1		Ready signal indicating TFU has space available in it's FIFO and is ready to be written to.
HCU Interface data and control signals			
Hcu_tfu_advdot	1		Signal indicating to the TFU that the HCU is ready to accept the next dot of data from TFU.
tfu_hcu_tdata	1	Out	Data from the TFU FIFO.
tfu_hcu_avail	1		Signal indicating valid data available from TFU FIFO.

27.3 CONFIGURATION REGISTERS

Table 191. TFU Configuration Registers

Address	register name	#bits	value	description
TFU_Base +			on	
			reset	
Control regist	ers			
0x00	Reset	1	1	A write to this register causes a reset of
				the TFU.
		ŀ		This register can be read to indicate the
				reset state:
				0 - reset in progress
				1 - reset not in progress.
0x04	Go	1	see	Writing 1 to this register starts the TFU.
			text	Writing 0 to this register halts the TFU.
				When Go is deasserted the state-
		ŀ		machines go to their idle states but all
		·		counters and configuration registers
		ŀ		keep their values.
				When Go is asserted all counters are
				reset, but configuration registers keep
				their values (i.e. they don't get reset).
				The TFU must be started before the TE
				is started.

				This register can be read to determine if
				the TFU is running
				(1 = running, 0 = stopped).
Setup reg	isters (constant during	process	sing of p	page)
0x08	XScale	8	1	Tag scale factor in X direction.
0x0C	XFracScale	8	1	Tag scale factor in X direction for the first dot in a line (must be programmed to be less than or equal to XScale)
0x10	TEByteCount	12	0	The number of bytes to be accepted from the TE per line. Once this number of bytes have been received subsequent bytes are ignored until there is a strobe on the te_tfu_wradvline
0x14	HCUDotCount	16	O	The number of (optionally) x-scaled dots per line to be supplied to the HCU. Once this number has been reached the remainder of the current FIFO byte is ignored.

27.4 DETAILED DESCRIPTION

5

The FIFO is a simple 16-byte store with read and write pointers, and a contents store, Figure 229. 16 bytes is sufficient to store a single 126 dot tag.

Each line a total of *TEByteCount* bytes is read into the FIFO. All subsequent bytes are ignored until there is a strobe on the *te_tfu_wradvline* signal, whereupon bytes for the next line are stored. On the HCU side, a total of *HCUDotCount* dots are produced at the output. Once this count is reached any more dots in the FIFO byte currently being processed are ignored. For the first dot in the next line the start of line scale factor, *XFracScale*, is used.

The behaviour of these signals and the control signals between the TFU and the TE and HCU is detailed below.

```
// Concurrently Executed Code:
                        // TE always allowed to write when there's either (a)
                 room
                            or
                                     (b)
                                               no
                                                        room
                                                                   and
                                                                            all
                        // bytes for that line have been received.
15
                        if ((FifoCntnts != FifoMax) OR (FifoCntnts == FifoMax
                 and ByteToRx == 0)) then
                           tfu_te_oktowrite = 1
                           tfu_te_oktowrite = 0
20

                           if(BitToTx == 1) then {
                               RepFrac = XFracScale
                               RdBit = 0
                               FifoRdPnt ++
35
                               FifoContents--
                               BitToTx = HCUDotCount
                           }
```

What is not detailed above is the fact that, since this is a circular buffer, both the fifo read and write-pointers wrap-around to zero after they reach two. Also not detailed is the fact that if there is a change of both the read and write-pointer in the same cycle, the fifo contents counter remains unchanged.

28 alftoner Compositor Unit (HCU)

28.1 OVERVIEW

The Halftoner Compositor Unit (HCU) produces dots for each nozzle in the destination printhead taking account of the page dimensions (including margins). The spot data and tag data are received in bi-level form while the pixel contone data received from the CFU must be dithered to a bi-level representation. The resultant 6 bi-level planes for each dot position on the page are then remapped to 6 output planes and output dot at a time (6 bits) to the next stage in the printing pipeline, namely the dead nozzle compensator (DNC).

28.2 DATA FLOW

5

15

20

25

30

Figure 230 shows a simple dot data flow high level block diagram of the HCU. The HCU reads contone data from the CFU, bi-level spot data from the SFU, and bi-level tag data from the TFU.

Dither matrices are read from the DRAM via the DIU. The calculated output dot (6 bits) is read by the DNC.

The HCU is given the page dimensions (including margins), and is only started once for the page. It does not need to be programmed in between bands or restarted for each band. The HCU will stall appropriately if its input buffers are starved. At the end of the page the HCU will continue to produce 0 for all dots as long as data is requested by the units further down the pipeline (this allows later units to conveniently flush pipelined data).

The HCU performs a linear processing of dots calculating the 6-bit output of a dot in each cycle. The mapping of 6 calculated bits to 6 output bits for each dot allows for such example mappings as compositing of the spot0 layer over the appropriate contone layer (typically black), the merging of CMY into K (if K is present in the printhead), the splitting of K into CMY dots if there is no K in the printhead, and the generation of a fixative output bitstream.

28.3 DRAM STORAGE REQUIREMENTS

SoPEC allows for a number of different dither matrix configurations up to 256 bytes wide. The dither matrix is stored in DRAM. Using either a single or double-buffer scheme a line of the dither matrix must be read in by the HCU over a SoPEC line time. SoPEC must produce 13824 dots per line for A4/Letter printing which takes 13824 cycles.

The following give the storage and bandwidths requirements for some of the possible configurations of the dither matrix.

- 4 Kbyte DRAM storage required for one 64x64 (preferred) byte dither matrix
- 6.25 Kbyte DRAM storage required for one 80x80 byte dither matrix
 - 16 Kbyte DRAM storage required for four 64x64 byte dither matrices
 - 64 Kbyte DRAM storage required for one 256x256 byte dither matrix

It takes 4 or 8 read accesses to load a line of dither matrix into the dither matrix buffer, depending on whether we're using a single or double buffer (configured by *DoubleLineBuff* register).

35 28.4 IMPLEMENTATION

A block diagram of the HCU is given in Figure 231.

28.4.1 Definition of I/O

Table 192. HCU port list and description

Port name	Pins	1/0	Description

Clocks and reset					
Pclk	1	In	System clock.		
prst_n	1	In	System reset, synchronous active low.		
PCU interface		<u> </u>			
pcu_hcu_sel	1	In	Block select from the PCU. When pcu_hcu_sel is high		
			both <i>pcu_adr</i> and <i>pcu_dataout</i> are valid.		
pcu_rwn	1	In	Common read/not-write signal from the PCU.		
pcu_adr[7:2]	6	ln	PCU address bus. Only 6 bits are required to decode the		
	1		address space for this block.		
pcu_dataout[31:0]	32	ln	Shared write data bus from the PCU.		
hcu_pcu_rdy	1	Out	Ready signal to the PCU. When hcu_pcu_rdy is high it		
	ŀ		indicates the last cycle of the access. For a write cycle		
			this means pcu_dataout has been registered by the block		
			and for a read cycle this means the data on		
			hcu_pcu_datain is valid.		
hcu_pcu_datain[31:0]	32	Out	Read data bus to the PCU.		
DIU interface					
hcu_diu_rreq	1	Out	HCU read request, active high. A read request must be		
			accompanied by a valid read address.		
diu_hcu_rack	1	ln	Acknowledge from DIU, active high. Indicates that a read		
	l		request has been accepted and the new read address		
,			can be placed on the address bus, hcu_diu_radr.		
hcu_diu_radr[21:5]	17	Out	HCU read address. 17 bits wide (256-bit aligned word).		
diu_hcu_rvalid	1	ln	Read data valid, active high. Indicates that valid read data		
			is now on the read data bus, <i>diu_data</i> .		
diu_data[63:0]	64	ln	Read data from DIU.		
CFU interface					
cfu_hcu_avail	1	In	Indicates valid data present on cfu_hcu_c[3-0]data lines.		
cfu_hcu_c0data[7:0]	8	ln	Pixel of data in contone plane 0.		
cfu_hcu_c1data[7:0]	8	ln	Pixel of data in contone plane 1.		
cfu_hcu_c2data[7:0]	8	ln	Pixel of data in contone plane 2.		
cfu_hcu_c3data[7:0]	8	In	Pixel of data in contone plane 3.		
hcu_cfu_advdot	1	Out	Informs the CFU that the HCU has captured the pixel		
			data on cfu_hcu_c[3-0]data lines and the CFU can now		
			place the next pixel on the data lines.		
SFU interface	•				
sfu_hcu_avail	1	ln	Indicates valid data present on sfu_hcu_sdata.		
sfu_hcu_sdata	1	ln	Bi-level dot data.		
hcu_sfu_advdot	1	Out	Informs the SFU that the HCU has captured the dot data		

			on sfu_hcu_sdata and the SFU can now place the next			
			dot on the data line.			
TFU interface						
tfu_hcu_avail	1	ln	Indicates valid data present on tfu_hcu_tdata.			
tfu_hcu_tdata	1	ln	Tag dot data.			
hcu_tfu_advdot	1	Out	Informs the TFU that the HCU has captured the dot data on <i>tfu_hcu_tdata</i> and the TFU can now place the next dot on the data line.			
DNC interface						
dnc_hcu_ready	1	ln	Indicates that DNC is ready to accept data from the HCU.			
hcu_dnc_avail	1	Out	Indicates valid data present on hcu_dnc_data.			
hcu_dnc_data[5:0]	6	Out	Output bi-level dot data in 6 ink planes.			

28.4.2 Configuration Registers

The configuration registers in the HCU are programmed via the PCU interface. Refer to section 21.8.2 on page 321 for the description of the protocol and timing diagrams for reading and writing registers in the HCU. Note that since addresses in SoPEC are byte aligned and the PCU only supports 32-bit register reads and writes, the lower 2 bits of the PCU address bus are not required to decode the address space for the HCU. When reading a register that is less than 32 bits wide zeros should be returned on the upper unused bit(s) of *hcu_pcu_datain*. The configuration registers of the HCU are listed in Table 193.

Table 193. HCU Registers

Address	Register Name	#bits	Value	Description
(HCU_base +)			on	
			Reset	
Control registers		I		
0x00	Reset	1	0x1	A write to this register
				causes a reset of the
				HCU.
0x04	Go	1	0x0	Writing 1 to this register
				starts the HCU. Writing 0
				to this register halts the
				HCU.
				When Go is asserted all
				counters, flags etc. are
	1			cleared or given their
				initial value, but
				configuration registers
				keep their values.

10

5

				Mhan Cala dagaaadad
				When Go is deasserted
				the state-machines go to
				their idle states but all
				counters and
				configuration registers
			-	keep their values.
				The HCU should be
				started <i>after</i> the CFU,
				SFU, TFU, and DNC.
				This register can be read
				to determine if the HCU is
				running
				(1 = running, 0 =
				stopped).
Setup registers (constant		!		
for during processing)				
0x10	AvailMask	4	0x0	Mask used to determine
				which of the dotgen units
				etc. are to be checked
				before a dot is generated
	·			by the HCU within the
·				specified margins for the
				specified color plane. If
				the specified dotgen unit
				is stalled, then the HCU
				will also stall.
				See Table for bit
				allocation and definition.
0x14	TMMask	4	0x0	Same as <i>AvailMask</i> , but
				used in the top margin
				area before the
				appropriate target page is
				reached.
0x18	PageMarginY	32	0x0000	The first line considered
	-		l .	to be off the page.
0x1C	MaxDot	16		This is the maximum dot
				number - 1 present
			ł	across a page. For
				example if a page
L	l	L	L	- Francisco de Caracteria de C

		Ï		contains 13824 dots, then
				MaxDot will be 13823.
0x20	TopMargin	32	0x0000	The first line on a page to
			0000	be considered within the
				target page for contone
				and spot data. (0 = first
				printed line of page)
0x24	BottomMargin	32	0x0000	The first line in the target
			0000	bottom margin for
				contone and spot data
				(i.e. first line after target
				page).
0x28	LeftMargin	16	0x0000	The first dot on a line
				within the target page for
				contone and spot data.
0x2C	RightMargin	16	0xFFF	The first dot on a line
			F	within the target right
				margin for contone and
				spot data.
0x30	TagTopMargin	32	0×0000	The first line on a page to
			0000	be considered within the
				target page for tag data.
				(0 = first printed line of
				page)
0x34	TagBottomMargin	32	0x0000	The first line in the target
			_ 0000	bottom margin for tag
				data (i.e. first line after
				target page).
0x38	TagLeftMargin	16	0x0000	The first dot on a line
				within the target page for
				tag data.
0x3C	TagRightMargin	16	0xFFF	The first dot on a line
		:	F	within the target right
				margin for tag data.
0x44	StartDMAdr[21:5]	17	0x0_	Points to the first 256-bit
			0000	word of the first line of the
				dither matrix in DRAM.
0x48	EndDMAdr[21:5]	17	0x0_	Points to the last address
			0000	of the group of four 256-
	1	4		L

		<u> </u>		bit reads (or 8 if single
				buffering) that reads in
				the last line of the dither
				matrix.
0x4C	LineIncrement	5	0x2	The number of 256-bit
0.40	Linemorement	٦	UXZ	words in DRAM from the
	į			
				start of one line of the
				dither matrix and the start
				of the next line, i.e. the
				value by which the DRAM
				address is incremented at
				the start of a line so that it
				points to the start of the
				next line of the dither
				matrix.
0x50	DMInitIndexC0	8	0x00	If using the single-buffer
				scheme this register
				represents the initial index
				within 256-byte dither
				matrix line buffer for
				contone plane 0. If using
				double-buffer scheme,
				only the 7 lsbs are used.
0x54	DMLwrIndexC0	8	0x00	If using the single-buffer
				scheme this register
				represents the lower
				index within 256-byte
				dither matrix line buffer for
	·			contone plane 0. If using
				double-buffer scheme,
				only the 7 lsbs are used.

				scheme, only the 7 lsbs
				are used.
0x80	DoubleLineBuf	1	0x1	Selects the dither line
				buffer mode to be single
				or double buffer.
				0 - single line buffer mode
		ŀ		1 - double line buffer
				mode
0x84 to 0x98	IOMappingLo	6x32	0x0000	The dot reorg mapping for
				output inks 0 to 5. For
				each ink's 64-bit
				IOMapping value,
	,			// // // // // // // // // // // // //
,				the low order 32 bits.
0x9C to 0xB0	lOMappingHi	6x32	$0 \times 0 0 0 0$	The dot reorg mapping for
DAGG TO GADG	l'Olvidppingi ii	0.02		output inks 0 to 5. For
			0000	each ink's 64-bit
				IOMapping value,
				IOMappingHi represents
				the high order 32 bits.
0xB4 to 0xC0	cpConstant	4x8	0x00	The constant contone
				value to output for
1				contone plane N when
				printing in the margin
				areas of the page. This
				value will typically be 0.
0xC4	sConstant	1	0x0	The constant bi-level
				value to output for spot
				when printing in the
				margin areas of the page.
				This value will typically be
				0.
0xC8	tConstant	1	0x0	The constant bi-level
			.i	

		Γ.		value to output for tag
				data when printing in the
				margin areas of the page.
				This value will typically be
				0.
0xCC	DitherConstant	8	0xFF	The constant value to use
				for dither matrix when the
				dither matrix is not
				available, i.e. when the
				signal <i>dm_avail</i> is 0. This
				value will typically be
				0xFF so that cpConstant
				can easily be 0x00 or
				0xFF without requiring a
				dither matrix
				(DitherConstant is
				primarily used for
				threshold dithering in the
				margin areas).

28.4.3 Control unit

5

10

20

The control unit is responsible for controlling the overall flow of the HCU. It is responsible for determining whether or not a dot will be generated in a given cycle, and what dot will actually be generated - including whether or not the dot is in a margin area, and what dither cell values should be used at the specific dot location. A block diagram of the control unit is shown in Figure 232.

The inputs to the control unit are a number of avail flags specifying whether or not a given dotgen unit is capable of supplying 'real' data in this cycle. The term 'real' refers to data generated from external sources, such as contone line buffers, bi-level line buffers, and tag plane buffers. Each dotgen unit informs the control unit whether or not a dot can be generated this cycle from real data. It must also check that the DNC is ready to receive data.

The contone/spot margin unit is responsible for determining whether the current dot coordinate is within the target contone/spot margins, and the tag margin unit is responsible for determining whether the current dot coordinate is within the target tag margins.

The dither matrix table interface provides the interface to DRAM for the generation of dither cell values that are used in the halftoning process in the contone dotgen unit.

28.4.3.1 Determine advdot

The HCU does not always require contone planes, bi-level or tag planes in order to produce a page. For example, a given page may not have a bi-level layer, or a tag layer. In addition, the contone and bi-level parts of a page are only required within the contone and bi-level page margins, and the tag part of a page is only required within the tag page margins. Thus output dots can be generated without contone, bi-level or tag data before the respective top margins of a page has been reached, and 0s are generated for all color planes after the end of the page has been reached (to allow later stages of the printing pipeline to flush).

Consequently the HCU has an *AvailMask* register that determines which of the various input avail flags should be taken notice of during the production of a page from the first line of the target page, and a *TMMask* register that has the same behaviour, but is used in the lines before the target page has been reached (i.e. inside the target top margin area). The dither matrix mask bit *TMask[0]* is the exception, it applies to all margins areas not just the top margin. Each bit in the

AvailMask refers to a particular avail bit: if the bit in the AvailMask register is set, then the corresponding avail bit must be 1 for the HCU to advance a dot. The bit to avail correspondence is shown in Table 194. Care should be taken with TMMask - if the particular data is not available after the top margin has been reached, then the HCU will stall. Note that the avail bits for contone and spot colors are ANDed with in_target_page after the target page area has been reached to allow dot production in the contone/spot margin areas without needing any data in the CFU and SFU. The avail bit for tag color is ANDed with in_tag_target_page after the target tag page area has been reached to allow dot production in the tag margin areas without needing any data in the TFU.

Table 194. Correspondence between bit in AvailMask and avail flag

bit # in AvailMask	avail flag	description
0	dm_avail	dither matrix data available
1	cp_avail	contone pixels available
2	s_avail	spot color available
3	tp_avail	tag plane available

Each of the input avail bits is processed with its appropriate mask bit and the after_top_margin flag (note the dither matrix is the exception it is processed with in_target_page). The output bits are ANDed together along with Go and output_buff_full (which specifies whether the output buffer is ready to receive a dot in this cycle) to form the output bit advdot. We also generate wr_advdot. In this way, if the output buffer is full or any of the specified avail flags is clear, the HCU will stall. When the end of the page is reached, in_page will be deasserted and the HCU will continue to produce 0 for all dots as long as the DNC requests data. A block diagram of the determine advdot unit is shown in Figure 233.

The advance dot block also determines if current page needs dither matrix, it indicates to the dither matrix table interface block via the *dm_read_enable* signal. If no dither is required in the margins or in the target page then *dm_read_enable* will be 0 and no dither will be read in for this page.

25 28.4.3.2 Position unit

5

10

15

20

30

35

The position unit is responsible for outputting the position of the current dot (curr_pos, curr_line) and whether or not this dot is the last dot of a line (advline). Both curr_pos and curr_line are set to 0 at reset or when Go transitions from 0 to 1. The position unit relies on the advdot input signal to advance through the dots on a page. Whenever an advdot pulse is received, curr_pos gets incremented. If curr_pos equals max_dot then an advline pulse is generated as this is the last dot in a line, curr_line gets incremented, and the curr_pos is reset to 0 to start counting the dots for the next line.

The position unit also generates a filtered version of *advline* called *dm_advline* to indicate to the dither matrix pointers to increment to the next line. The *dm_advline* is only incremented when dither is required for that line.

```
if ((after_top_margin AND avail_mask[0]) OR tm_mask[0]) then
  dm_advline = advline
else
  dm advline = 0
```

5 28.4.3.3 Margin unit

20

25

The responsibility of the margin unit is to determine whether the specific dot coordinate is within the page at all, within the target page or in a margin area (see Figure 234). This unit is instantiated for both the contone/spot margin unit and the tag margin unit.

The margin unit takes the current dot and line position, and returns three flags.

- the first, in_page is 1 if the current dot is within the page, and 0 if it is outside the page.
 - the second flag, *in_target_page*, is 1 if the dot coordinate is within the target page area of the page, and 0 if it is within the target top/left/bottom/right margins.
 - the third flag, after_top_margin, is 1 if the current dot is below the target top margin, and 0 if it is within the target top margin.
- 15 A block diagram of the margin unit is shown in Figure 235.

28.4.3.4 Dither matrix table interface

The dither matrix table interface provides the interface to DRAM for the generation of dither cell values that are used in the halftoning process in the contone dotgen unit. The control flag dm_read_enable enables the reading of the dither matrix table line structure from DRAM. If dm_read_enable is 0, the dither matrix is not specified in DRAM and no DRAM accesses are attempted. The dither matrix table interface has an output flag dm_avail which specifies if the current line of the specified matrix is available. The HCU can be directed to stall when dm_avail is 0 by setting the appropriate bit in the HCU's AvailMask or TMMask registers. When dm_avail is 0 the value in the DitherConstant register is used as the dither cell values that are output to the contone dotgen unit.

The dither matrix table interface consists of a state machine that interfaces to the DRAM interface, a dither matrix buffer that provides dither matrix values, and a unit to generate the addresses for reading the buffer. Figure 236 shows a block diagram of the dither matrix table interface.

28.4.3.5 Dither data structure in DRAM

The dither matrix is stored in DRAM in 256-bit words, transferred to the HCU in 64-bit words and consumed by the HCU in bytes. Table 195 shows the 64-bit words mapping to 256-bit word addresses, and Table 196 shows the 8-bits dither value mapping in the 64-bits word.

Table 195.	Dither	Data	stored i	n DRAM
------------	--------	------	----------	--------

Address[21:5]	Data[255:	Data[255:0]					
00000	D3	D2	D1	D0			
	[255:192]	[191:128]	[127:64]	[63:0]			
00001	D7	D6	D5	D4			
	[255:192]	[191:128]	[127:64]	[63:0]			
00010	D11	D10	D9	D8			

	[255:192]	[191:128]	[127:64]	[63:0]
00011	D15	D14	D13	D12
	[255:192]	[191:128]	[127:64]	[63:0]
00100	D19	D18	D17	D16
	[255:192]	[191:128]	[127:64]	[63:0]
etc				

When the HCU first requests data from DRAM, the 64-bits word transfer order will be D0,D1,D2,D3. On the second request the transfer order will be D4,D5,D6,D7 and so on for other requests.

Table 196. Dither data stored in HCUs line buffer

				etc.	etc.

28.4.3.5.1 Dither matrix buffer

The state machine loads dither matrix table data a line at a time from DRAM and stores it in a buffer. A single line of the dither matrix is either 256 or 128 8-bit entries, depending on the programmable bit *DoubleLineBuf*. If this bit is enabled, a double-buffer mechanism is employed such that while one buffer is read from for the current line's dither matrix data (8 bits representing a single dither matrix entry), the other buffer is being written to with the next line's dither matrix data (64-bits at a time). Alternatively, the single buffer scheme can be used, where the data must be loaded at the end of the line, thus incurring a delay.

The single/double buffer is implemented using a 256 byte 3-port register array, two reads, one write port, with the reads clocked at double the system clock rate (320MHz) allowing 4 reads per clock cycle.

The dither matrix buffer unit also provides the mechanism for keeping track of the current read and write buffers, and providing the mechanism such that a buffer cannot be read from until it has been written to. In this case, each buffer is a line of the dither matrix, i.e. 256 or 128 bytes. The dither matrix buffer maintains a read and write pointer for the dither matrix. The output value dm_avail is derived by comparing the read and write pointers to determine when the dither matrix is not empty. The write pointer wr_adr is incremented each time a 64-bit word is written to the dither matrix buffer and the read pointer rd_ptr is incremented each time $dm_advline$ is received. If $double_line_buf$ is 0 the rd_ptr will increment by 2, otherwise it will increment by 1. If the dither matrix buffer is full then no further writes will be allowed ($buff_full = 1$), or if the buffer is empty no further buffer reads are allowed ($buff_emp = 1$).

The read addresses are byte aligned and are generated by the read address generator. A single dither matrix entry is represented by 8 bits and an entry is read for each of the four contone planes in parallel. If double buffer is used (double_line_buf=1) the read address is derived from 7-bit address from the read address generator and 1-bit from the read pointer. If double_line_buf=0 then the read address is the full 8-bits from the read address generator.

25 28.4.3.5.2 Read address generator

5

10

15

30

For each contone plane there is a initial, lower and upper index to be used when reading dither cell values from the dither matrix double buffer. The read address for each plane is used to select a byte from the current 256-byte read buffer. When *Go* gets set (0 to 1 transition), or at the end of a line, the read addresses are set to their corresponding initial index. Otherwise, the read address generator relies on *advdot* to advance the addresses within the inclusive range specified the lower and upper indices, represented by the following pseudocode:

```
if (advdot == 1) then
    if (advline == 1) then

rd_adr = dm_init_index
elsif (rd_adr == dm_upr_index) then
    rd_adr = dm_lwr_index
else
    rd_adr ++

else
    rd_adr = rd_adr

28.4.3.5.3 State machine
```

The dither matrix is read from DRAM in single 256-bit accesses, receiving the data from the DIU over 4 clock cycles (64-bits per cycle). The protocol and timing for read accesses to DRAM is described in section 20.9.1 on page 240. Read accesses to DRAM are implemented by means of the state machine described in Figure 238.

All counters and flags should be cleared after reset or when *Go* transitions from 0 to 1. While the *Go* bit is 1, the state machine relies on the *dm_read_enable* bit to tell it whether to attempt to read dither matrix data from DRAM. When *dm_read_enable* is clear, the state machine does nothing and remains in the idle state. When *dm_read_enable* is set, the state machine continues to load dither matrix data, 256-bits at a time (received over 4 clock cycles, 64 bits per cycle), while there is space available in the dither matrix buffer, (*buff_full* !=1).

The read address and *line_start_adr* are initially set to *start_dm_adr*. The read address gets incremented after each read access. It takes 4 or 8 read accesses to load a line of dither matrix into the dither matrix buffer, depending on whether we're using a single or double buffer. A count is kept of the accesses to DRAM. When a read access completes and *access_count* equals 3 or 7, a line of dither matrix has just been loaded from and the read address is updated to *line_start_adr* plus *line_increment* so it points to the start of the next line of dither matrix. (*line_start_adr* is also updated to this value). If the read address equals *end_dm_adr* then the next read address will be *start_dm_adr*, thus the read address wraps to point to the start of the area in DRAM where the dither matrix is stored.

The write address for the dither matrix buffer is implemented by means of a modulo-32 counter that is initially set to 0 and incremented when *diu hcu rvalid* is asserted.

Figure 237 shows an example of setting *start_dm_adr* and *end_dm_adr* values in relation to the line increment and double line buffer settings. The calculation of *end_dm_adr* is

28.4.4 Contone dotgen unit

15

35

40

The contone dotgen unit is responsible for producing a dot in up to 4 color planes per cycle. The contone dotgen unit also produces a *cp_avail* flag which specifies whether or not contone pixels are currently available, and the output *hcu_cfu_advdot* to request the CFU to provide the next contone pixel in up to 4 color planes.

The block diagram for the contone dotgen unit is shown in Figure 239.

A dither unit provides the functionality for dithering a single contone plane. The contone image is only defined within the contone/spot margin area. As a result, if the input flag *in_target_page* is 0, then a constant contone pixel value is used for the pixel instead of the contone plane.

The resultant contone pixel is then halftoned. The dither value to be used in the halftoning process is provided by the control data unit. The halftoning process involves a comparison between a pixel value and its corresponding dither value. If the 8-bit contone value is *greater than or equal* to the 8-bit dither matrix value a 1 is output. If not, then a 0 is output. This means each entry in the dither matrix is in the range 1-255 (0 is not used).

Note that constant use is dependent on the <code>in_target_page</code> signal only, if <code>in_target_page</code> is 1 then the <code>cfu_hcu_c*_data</code> should be allowed to pass through, regardless of the stalling behaviour or the <code>avail_mask[1]</code> setting. This allows a constant value to be setup on the CFU output data, and the use of different constants while inside and outside the target page. The <code>hcu_cfu_advdot</code> will always be zero if the <code>avail_mask[1]</code> is zero.

28.4.5 Spot dotgen unit

5

10

15

20

35

40

The spot dotgen unit is responsible for producing a dot of bi-level data per cycle. It deals with bi-level data (and therefore does not need to halftone) that comes from the LBD via the SFU. Like the contone layer, the bi-level spot layer is only defined within the contone/spot margin area. As a result, if input flag *in_target_page* is 0, then a constant dot value (typically this would be 0) is used for the output dot.

The spot dotgen unit also produces a *s_avail* flag which specifies whether or not spot dots are currently available for this spot plane, and the output *hcu_sfu_advdot* to request the SFU to provide the next bi-level data value. The spot dotgen unit can be represented by the following pseudocode:

Note that constant use is dependent on the <code>in_target_page</code> signal only, if <code>in_target_page</code> is 1 then the <code>sfu_hcu_data</code> should be allowed to pass through, regardless of the stalling behaviour or the <code>avail_mask</code> setting. This allows a constant value to be setup on the SFU output data, and the use of different constants while inside and outside the target page. The <code>hcu_sfu_advdot</code> will always be zero if the <code>avail_mask[2]</code> is zero.

28.4.6 Tag dotgen unit

This unit is very similar to the spot dotgen unit (see Section 28.4.5) in that it deals with bi-level data, in this case from the TE via the TFU. The tag layer is only defined within the tag margin area. As a result, if input flag *in_tag_target_page* is 0, then a constant dot value, *tp_constant* (typically this would be 0), is used for the output dot. The tagplane dotgen unit also produces a

tp_avail flag which specifies whether or not tag dots are currently available for the tagplane, and the output hcu_tfu_advdot to request the TFU to provide the next bi-level data value.

The hcu_tfu_advdot generation is similar to the SFU and CFU, except it depends only on in_target_page and advdot. It does not take into account the avail mask when inside the target page.

28.4.7 Dot reorg unit

5

The dot reorg unit provides a means of mapping the bi-level dithered data, the spot0 color, and the tag data to output inks in the actual printhead. Each dot reorg unit takes a set of 6 1-bit inputs and produces a single bit output that represents the output dot for that color plane.

- The output bit is a logical combination of any or all of the input bits. This allows the spot color to be placed in any output color plane (including infrared for testing purposes), black to be merged into cyan, magenta and yellow (in the case of no black ink in the Memjet printhead), and tag dot data to be placed in a visible plane. An output for fixative can readily be generated by simply combining desired input bits.
- The dot reorg unit contains a 64-bit lookup to allow complete freedom with regards to mapping. Since all possible combinations of input bits are accounted for in the 64 bit lookup, a given dot reorg unit can take the mapping of other reorg units into account. For example, a black plane reorg unit may produce a 1 only if the contone plane 3 or spot color inputs are set (this effectively composites black bi-level over the contone). A fixative reorg unit may generate a 1 if any 2 of the output color planes is set (taking into account the mappings produced by the other reorg units). If dead nozzle replacement is to be used (see section 29.4.2 on page 473), the dot reorg can be programmed to direct the dots of the specified color into the main plane, and 0 into the other. If a nozzle is then marked as dead in the DNC, swapping the bits between the planes will result in 0 in the dead nozzle, and the required data in the other plane.
- If dead nozzle replacement is to be used, and there are no tags, the TE can be programmed with the position of dead nozzles and the resultant pattern used to direct dots into the specified nozzle row. If only fixed background TFS is to be used, a limited number of nozzles can be replaced. If variable tag data is to be used to specify dead nozzles, then large numbers of dead nozzles can be readily compensated for.
- The dot reorg unit can be used to average out the nozzle usage when two rows of nozzles share the same ink and tag encoding is not being used. The TE can be programmed to produce a regular pattern (e.g. 0101 on one line, and 1010 on the next) and this pattern can be used as a directive as to direct dots into the specified nozzle row.
- Each reorg unit contains a 64-bit *IOMapping* value programmable as two 32-bit HCU registers, and a set of selection logic based on the 6-bit dot input (2⁶ = 64 bits), as shown in Figure 240. The mapping of input bits to each of the 6 selection bits is as defined in Table 197.

Table 197. Mapping of input bits to 6 selection bits

address bit	tied to	likely
of lookup		interpretation

0	bi-level dot from contone layer 0	cyan
1	bi-level dot from contone layer 1	magenta
2	bi-level dot from contone layer 2	yellow
3	bi-level dot from contone layer 3	black
4	bi-level spot0 dot	black
5	bi-level tag dot	infra-red

28.4.8 Output buffer

The output buffer de-couples the stalling behaviour of the feeder units from the stalling behaviour of the DNC. The larger the buffer the greater de-coupling. Currently the output buffer size is 2, but could be increased if needed at the cost of extra area.

If the *Go* bit is set to 0 no read or write of the output buffer is permitted. On a low to high transition of the *Go* bit the contents of the output buffer are cleared.

The output buffer also implements the interface logic to the DNC. If there is data in the output buffer the *hcu_dnc_avail* signal will be 1, otherwise is will be 0. If both *hcu_dnc_avail* and *dnc_hcu_ready* are 1 then data is read from the output buffer.

On the write side if there is space available in the output buffer the logic indicates to the control unit via the *output_buff_full* signal. The control unit will then allow writes to the output buffer via the *wr_advdot* signal. If the writes to the output buffer are after the end of a page (indicated by *in_page* equal to 0) then all dots written into the output buffer are set to zero.

28.4.8.1 HCU to DNC interface

Figure 241 shows the timing diagram and representative logic of the HCU to DNC interface. The hcu_dnc_avail signal indicate to the DNC that the HCU has data available. The dnc_hcu_ready signal indicates to the HCU that the DNC is ready to accept data. When both signals are high data is transferred from the HCU to the DNC. Once the HCU indicates it has data available (setting the hcu_dnc_avail signal high) it can only set the hcu_dnc_avail low again after a dot is accepted by the DNC.

28.4.9 Feeder to HCU interfaces

Figure 242 shows the feeder unit to HCU interface timing diagram, and Figure 243 shows representative logic of the interface with the register positions. sfu_hcu_data and sfu_hcu_avail are always registered while the sfu_hcu_advdot is not. The hcu_sfu_avail signal indicates to the HCU that the feeder unit has data available, and sfu_hcu_advdot indicates to the feeder unit that the HCU has captured the last dot. The HCU can never produce an advance dot pulse while the avail is low. The diagrams show the example of the SFU to HCU interface, but the same interface is used for the other feeder units TFU and CFU.

30 29 Dead Nozzie Compensator (DNC)

29.1 OVERVIEW

25

The Dead Nozzle Compensator (DNC) is responsible for adjusting Memjet dot data to take account of non-functioning nozzles in the Memjet printhead. Input dot data is supplied from the

HCU, and the corrected dot data is passed out to the DWU. The high level data path is shown by the block diagram in Figure 244.

The DNC compensates for a dead nozzles by performing the following operations:

- Dead nozzle removal, i.e. turn the nozzle off
- 5 Ink replacement by direct substitution i.e. K -> K
 - Ink replacement by indirect substitution i.e. K -> CMY
 - Error diffusion to adjacent nozzles
 - Fixative corrections

The DNC is required to efficiently support up to 5% dead nozzles, under the expected DRAM bandwidth allocation, with no restriction on where dead nozzles are located and handle any fixative correction due to nozzle compensations. Performance must degrade gracefully after 5% dead nozzles.

29.2 DEAD NOZZLE IDENTIFICATION

25

30

35

15 is represented by a 10-bit delta encoded format, where the 10-bit value defines the number of dots between dead nozzle columns¹⁹. With the delta information it also reads the 6-bit dead nozzle mask (dn_mask) for the defined dead nozzle position. Each bit in the dn_mask corresponds to an ink plane. A set bit indicates that the nozzle for the corresponding ink plane is dead. The dead nozzle table format is shown in Figure 245. The DNC reads dead nozzle information from DRAM in single 256-bit accesses. A 10-bit delta encoding scheme is chosen so that each table entry is 16 bits wide, and 16 entries fit exactly in each 256-bit read. Using 10-bit delta encoding means that the maximum distance between dead nozzle columns is 1023 dots. It is possible that dead nozzles may be spaced further than 1023 dots from each other, so a null dead nozzle identifier is required. A null dead nozzle identifier is defined as a 6-bit dn_mask of all zeros. These null dead nozzle identifiers should also be used so that:

- the dead nozzle table is a multiple of 16 entries (so that it is aligned to the 256-bit DRAM locations)
 - the dead nozzle table spans the complete length of the line, i.e.
 the first entry dead nozzle table should have a delta from the
 first nozzle column in a line and the last entry in the dead nozzle
 table should correspond to the last nozzle column in a line.

Note that the DNC deals with the width of a page. This may or may not be the same as the width of the printhead (the PHI may introduce some margining to the page so that its dot output matches the width of the printhead). Care must be taken when programming the dead nozzle table so that dead nozzle positions are correctly specified with respect to the page and printhead.

29.3 DRAM STORAGE AND BANDWIDTH REQUIREMENT

The memory required is largely a factor of the number of dead nozzles present in the printhead (which in turn is a factor of the printhead size). The DNC is required to read a 16-bit entry from the

¹⁹ for a 10-bit delta value of d, if the current column n is a dead nozzle column then the next dead nozzle column is given by n + (d + 1).

dead nozzle table for every dead nozzle. Table 198 shows the DRAM storage and average²⁰ bandwidth requirements for the DNC for different percentages of dead nozzles and different page sizes.

Table 198. Dead Nozzle storage and average bandwidth requirements

Page siz	e % Dead	Dead nozzl	e table
	Nozzles	· ·	
		Memory	Bandwidth
		(KBytes)	. (bits/cycle)
A4 ^a	5%	1.4°	0.8 ^d
	10%	2.7	1.6
	15%	4.1	2.4
А3 ^б	5%	1.9	0.8
	10%	3.8	1.6
	15%	5.7	2.4

- a. Bi-lithic printhead has 13824 nozzles per color providing full bleed printing for A4/Letter
 - b. Bi-lithic printhead has 19488 nozzles per color providing full bleed printing for A3
 - c. 16 bits x 13824 nozzles x 0.05 dead
 - d. (16 bits read / 20 cycles) = 0.8 bits/cycle

29.4 NOZZLE COMPENSATION

5

20

25

DNC receives 6 bits of dot information every cycle from the HCU, 1 bit per color plane. When the dot position corresponds to a dead nozzle column, the associated 6-bit dn_mask indicates which ink plane(s) contains a dead nozzle(s). The DNC first deletes dots destined for the dead nozzle. It then replaces those dead dots, either by placing the data destined for the dead nozzle into an adjacent ink plane (direct substitution) or into a number of ink planes (indirect substitution). After ink replacement, if a dead nozzle is made active again then the DNC performs error diffusion. Finally, following the dead nozzle compensation mechanisms the fixative, if present, may need to be adjusted due to new nozzles being activated, or dead nozzles being removed.

29.4.1 Dead nozzle removal

If a nozzle is defined as dead, then the first action for the DNC is to turn off (zeroing) the dot data destined for that nozzle. This is done by a bit-wise ANDing of the inverse of the *dn_mask* with the dot value.

29.4.2 Ink replacement

Ink replacement is a mechanism where data destined for the dead nozzle is placed into an adjacent ink plane of the same color (direct substitution, i.e. K -> K_{alternative}), or placed into a number of ink planes, the combination of which produces the desired color (indirect substitution, i.e. K -> CMY). Ink replacement is performed by filtering out ink belonging to nozzles that are

²⁰Average bandwidth assumes an even spread of dead nozzles. Clumps of dead nozzles may cause delays due to insufficient available DRAM bandwidth. These delays will occur every line causing an accumulative delay over a page.

dead and then adding back in an appropriately calculated pattern. This two step process allows the optional re-inclusion of the ink data into the original dead nozzle position to be subsequently error diffused. In the general case, fixative data destined for a dead nozzle should not be left active intending it to be later diffused.

The ink replacement mechanism has 6 ink replacement patterns, one per ink plane, programmable by the CPU. The dead nozzle mask is ANDed with the dot data to see if there are any planes where the dot is active but the corresponding nozzle is dead. The resultant value forms an enable, on a per ink basis, for the ink replacement process. If replacement is enabled for a particular ink, the values from the corresponding replacement pattern register are ORed into the dot data. The output of the ink replacement process is then filtered so that error diffusion is only allowed for the planes in which error diffusion is enabled. The output of the ink replacement logic is ORed with the resultant dot after dead nozzle removal. See Figure in page 565 on page Error!

Bookmark not defined. for implementation details.

For example if we consider the printhead color configuration C,M,Y,K_1,K_2,IR and the input dot data from the HCU is b101100. Assuming that the K_1 ink plane and IR ink plane for this position are dead so the dead nozzle mask is b000101. The DNC first removes the dead nozzle by zeroing the K_1 plane to produce b101000. Then the dead nozzle mask is ANDed with the dot data to give b000100 which selects the ink replacement pattern for K_1 (in this case the ink replacement pattern for K_1 is configured as b000010, i.e. ink replacement into the K_2 plane). Providing error diffusion for K_2 is enabled, the output from the ink replacement process is b000010. This is ORed with the output of dead nozzle removal to produce the resultant dot b101010. As can be seen the dot data in the defective K_1 nozzle was removed and replaced by a dot in the adjacent K_2 nozzle in the same dot position, i.e. direct substitution.

In the example above the K_1 ink plane could be compensated for by indirect substitution, in which case ink replacement pattern for K_1 would be configured as b111000 (substitution into the CMY color planes), and this is ORed with the output of dead nozzle removal to produce the resultant dot b111000. Here the dot data in the defective K_1 ink plane was removed and placed into the CMY ink planes.

29.4.3 Error diffusion

15

20

25

35

30 Based on the programming of the lookup table the dead nozzle may be left active after ink replacement. In such cases the DNC can compensate using error diffusion. Error diffusion is a mechanism where dead nozzle dot data is diffused to adjacent dots.

When a dot is active and its destined nozzle is dead, the DNC will attempt to place the data into an adjacent dot position, if one is inactive. If both dots are inactive then the choice is arbitrary, and is determined by a pseudo random bit generator. If both neighbor dots are already active then the bit cannot be compensated by diffusion.

Since the DNC needs to look at neighboring dots to determine where to place the new bit (if required), the DNC works on a set of 3 dots at a time. For any given set of 3 dots, the first dot

received from the HCU is referred to as dot A, and the second as dot B, and the third as dot C. The relationship is shown in Figure 246.

For any given set of dots ABC, only B can be compensated for by error diffusion if B is defined as dead. A 1 in dot B will be diffused into either dot A or dot C if possible. If there is already a 1 in dot A or dot C then a 1 in dot B cannot be diffused into that dot.

The DNC must support adjacent dead nozzles. Thus if dot A is defined as dead and has previously been compensated for by error diffusion, then the dot data from dot B should not be diffused into dot A. Similarly, if dot C is defined as dead, then dot data from dot B should not be diffused into dot C.

- 10 Error diffusion should not cross line boundaries. If dot B contains a dead nozzle and is the first dot in a line then dot A represents the last dot from the previous line. In this case an active bit on a dead nozzle of dot B should not be diffused into dot A. Similarly, if dot B contains a dead nozzle and is the last dot in a line then dot C represents the first dot of the next line. In this case an active bit on a dead nozzle of dot B should not be diffused into dot C.
- 15 Thus, as a rule, a 1 in dot B cannot be diffused into dot A if
 - a 1 is already present in dot A,
 - dot A is defined as dead,

5

30

35

or dot A is the last dot in a line.

Similarly, a 1 in dot B cannot be diffused into dot C if

- 20 a 1 is already present in dot C,
 - dot C is defined as dead,
 - or dot C is the first dot in a line.

If B is defined to be dead and the dot value for B is 0, then no compensation needs to be done and dots A and C do not need to be changed.

- If B is defined to be dead and the dot value for B is 1, then B is changed to 0 and the DNC attempts to place the 1 from B into either A or C:
 - If the dot can be placed into both A and C, then the DNC must choose between them. The preference is given by the current output from the random bit generator, 0 for "prefer left" (dot A) or 1 for "prefer right" (dot C).
 - If dot can be placed into only one of A and C, then the 1 from B is placed into that position.
 - If dot cannot be placed into either one of A or C, then the DNC cannot place the dot in either position.

Table 199. Error Diffusion Truth Table when dot B is dead

Input	Output					
A OR A dead		C OR C dead	Rand`a	A	B	C

OR		OR				
A last in line		C first in line				
0	0	0	X	A input	0	C input
0	0	1	X	A input	0	C input
0	1	0	Ō	1`b	0	C input
0	1	0	1	A input	0	1
0	1	1	X	1	0	C input
1	0	0	X	A input	0	C input
1	0	1	X	A input	0	C input
1	1	0	×	A input	0	1
1	1	1	×	A input	0	C input

Table 199 shows the truth table for DNC error diffusion operation when dot B is defined as dead.

- a. Output from random bit generator. Determines direction of error diffusion (0 = left, 1 = right)
- b. Bold emphasis is used to show the DNC inserted a 1

The random bit value used to arbitrarily select the direction of diffusion is generated by a 32-bit maximum length random bit generator. The generator generates a new bit for each dot in a line regardless of whether the dot is dead or not. The random bit generator can be initialized with a 32-bit programmable seed value.

29.4.4 Fixative correction

5

10

15

20

After the dead nozzle compensation methods have been applied to the dot data, the fixative, if present, may need to be adjusted due to new nozzles being activated, or dead nozzles being removed. For each output dot the DNC determines if fixative is required (using the *FixativeRequiredMask* register) for the new compensated dot data word and whether fixative is activated already for that dot. For the DNC to do so it needs to know the color plane that has fixative, this is specified by the *FixativeMask1* configuration register. Table 200 indicates the actions to take based on these calculations.

Table 200. Truth table for fixative correction

Fixative Present	Fixative required	Action
1	1	Output dot as is.
1	0	Clear fixative plane.
0	1	Attempt to add fixative.
0	0	Output dot as is.

The DNC also allows the specification of another fixative plane, specified by the *FixativeMask2* configuration register, with *FixativeMask1* having the higher priority over *FixativeMask2*. When attempting to add fixative the DNC first tries to add it into the planes defined by *FixativeMask1*. However, if any of these planes is dead then it tries to add fixative by placing it into the planes defined by *FixativeMask2*.

Note that the fixative defined by FixativeMask1 and FixativeMask2 could possibly be multi-part fixative, i.e. 2 bits could be set in FixativeMask1 with the fixative being a combination of both inks.

29.5 IMPLEMENTATION

A block diagram of the DNC is shown in Figure 247.

5 29.5.1 Definitions of I/O

Table 201. DNC port list and description

Port name	Pins	1/0	Description
Clocks and Resets	<u>. </u>		
Pclk	1	ln	System Clock.
prst_n	1	In	System reset, synchronous active low.
PCU interface	<u> </u>		
pcu_dnc_sel	1	In	Block select from the PCU. When pcu_dnc_sel is
			high both <i>pcu_adr</i> and <i>pcu_dataout</i> are valid.
pcu_rwn	1	In	Common read/not-write signal from the PCU.
pcu_adr[6:2]	5	ln	PCU address bus. Only 5 bits are required to
			decode the address space for this block.
pcu_dataout[31:0]	32	In	Shared write data bus from the PCU.
dnc_pcu_rdy	1	Out	Ready signal to the PCU. When dnc_pcu_rdy is
			high it indicates the last cycle of the access. For a
			write cycle this means <i>pcu_dataout</i> has been
			registered by the block and for a read cycle this
			means the data on dnc_pcu_datain is valid.
dnc_pcu_datain[31:0]	32	Out	Read data bus to the PCU.
DIU interface			
dnc_diu_rreq	1	Out	DNC unit requests DRAM read. A read request
			must be accompanied by a valid read address.
dnc_diu_radr[21:5]	17	Out	Read address to DIU, 256-bit word aligned.
diu_dnc_rack	1	In	Acknowledge from DIU that read request has
			been accepted and new read address can be
			placed on <i>dnc_diu_radr</i>
diu_dnc_rvalid	1	In	Read data valid, active high. Indicates that valid
			read data is now on the read data bus, diu_data.
diu_data[63:0]	64	ln	Read data from DIU.
HCU interface			
dnc_hcu_ready	1	Out	Indicates that DNC is ready to accept data from the HCU.
hcu_dnc_avail	1	In	Indicates valid data present on hcu_dnc_data.
hcu_dnc_data[5:0]	6	ln	Output bi-level dot data in 6 ink planes.

DWU interface			
dwu_dnc_ready	1	ln	Indicates that DWU is ready to accept data from
			the DNC.
dnc_dwu_avail	1	Out	Indicates valid data present on dnc_dwu_data.
dnc_dwu_data[5:0]	6	Out	Output bi-level dot data in 6 ink planes.

29.5.2 Configuration registers

5

The configuration registers in the DNC are programmed via the PCU interface. Refer to section 21.8.2 on page 321 for the description of the protocol and timing diagrams for reading and writing registers in the DNC. Note that since addresses in SoPEC are byte aligned and the PCU only supports 32-bit register reads and writes, the lower 2 bits of the PCU address bus are not required to decode the address space for the DNC. When reading a register that is less than 32 bits wide zeros should be returned on the upper unused bit(s) of *dnc_pcu_datain*. Table 202 lists the configuration registers in the DNC.

10 Table 202. DNC configuration registers

Address (DNC_base +)	Register name	#bits	Value on reset	Description
Control register	s .			A CONTRACTOR OF THE CONTRACTOR
0x00	Reset	1	0x1	A write to this register causes a reset of the DNC.
0x04	Go	1	0x0	Writing 1 to this register starts the DNC. Writing 0 to this register halts the DNC. When <i>Go</i> is asserted all counters, flags etc. are cleared or given their initial value, but configuration registers keep their values. When <i>Go</i> is deasserted the statemachines go to their idle states but all counters and configuration registers keep their values. This register can be read to determine if the DNC is running (1 = running, 0 = stopped).
Setup registers	(constant during	oroces	ssing)	
0x10	MaxDot 	16	0x0000	This is the maximum dot number - 1 present across a page. For example if a page contains 13824 dots, then <i>MaxDot</i> will be 13823.

				Note that this number may or may not
				be the same as the number of dots
				across the printhead as some margining
				may be introduced in the PHI.
0x14	LSFR	32	0×0000_	The current value of the LFSR register
0.14	LOFIX	32	0000	_
			0000	used as the 32-bit maximum length
				random bit generator.
				Users can write to this register to
				program a seed value for the 32-bit
				maximum length random bit generator.
				Must not be all 1s for taps implemented
				in XNOR form. (It is expected that
				writing a seed value will not occur during
				the operation of the LFSR).
				This LSFR value could also have a
				possible use as a random source in
				program code.
0x20	FixativeMask1	6	0x00	Defines the higher priority fixative
	,			plane(s). Bit 0 represents the settings
				for plane 0, bit 1 for plane 1 etc. For
				each bit:
				1 = the ink plane contains fixative.
,				0 = the ink plane does not contain
				fixative.
0x24	FixativeMask2	6	0x00	Defines the lower priority fixative
				plane(s). Bit 0 represents the settings
				for plane 0, bit 1 for plane 1 etc. Used
				only when <i>FixativeMask1</i> planes are
				dead. For each bit:
				1 = the ink plane contains fixative.
				0 = the ink plane does not contain
				fixative.
0x28	FixativeRequired	6	0x00	Identifies the ink planes that require
	Mask			fixative. Bit 0 represents the settings for
				plane 0, bit 1 for plane 1 etc. For each
				bit:
				1 = the ink plane requires fixative.
				· '
				0 = the ink plane does not require
		l	L	fixative (e.g. ink is self-fixing)

0x30	DnTableStartAdr[17	0x0_0000	Start address of Dead Nozzle Table in
	21:5]			DRAM, specified in 256-bit words.
0x34	DnTableEndAdr[17	0x0 0000	End address of Dead Nozzle Table in
	21:5]			DRAM, specified in 256-bit words, i.e.
				the location containing the last entry in
				the Dead Nozzle Table.
				The Dead Nozzle Table should be
				aligned to a 256-bit boundary, if
				necessary it can be padded with null
			1	entries.
0x40 - 0x54	PlaneReplacePat	6×6	0x00	Defines the ink replacement pattern for
	tern[5:0]	0.0		each of the 6 ink planes.
	1011[0:0]			PlaneReplacePattern[0] is the ink
				replacement pattern for plane 0,
				PlaneReplacePattern[1] is the ink
			:	replacement pattern for plane 1, etc.
				For each 6-bit replacement pattern for a
				plane, a 1 in any bit positions indicates
				the alternative ink planes to be used for
0,50	Differentia			this plane.
0x58	DiffuseEnable	6	0x3F	Defines whether, after ink replacement,
				error diffusion is allowed to be
				performed on each plane.
]				Bit 0 represents the settings for plane 0,
				bit 1 for plane 1 etc. For each bit:
				1 = error diffusion is enabled
			_ <u></u> -	0 = error diffusion is disabled
Debug registers				
0x60	DncOutputDebug	8	N/A	Bit 7 = dwu_dnc_ready
				Bit 6 = dnc_dwu_avail
				Bits 5-0 = dnc_dwu_data
0x64	DncReplaceDeb	14	N/A	Bit 13 = edu_ready
	ug			Bit 12 = <i>iru_avail</i>
				Bits 11-6 = iru_dn_mask
				Bits 5-0 = <i>iru_data</i>
0x68	DncDiffuseDebu	14	N/A	Bit 13 = dwu_dnc_ready
	g			Bit 12 = <i>dnc_dwu_avail</i>
				Bits 11-6 = edu_dn_mask

		·		

29.5.3 Ink replacement unit

Figure 248 shows a sub-block diagram for the ink replacement unit.

29.5.3.1 Control unit

The control unit is responsible for reading the dead nozzle table from DRAM and making it available to the DNC via the dead nozzle FIFO. The dead nozzle table is read from DRAM in single 256-bit accesses, receiving the data from the DIU over 4 clock cycles (64-bits per cycle). The protocol and timing for read accesses to DRAM is described in section 20.9.1 on page 240. Reading from DRAM is implemented by means of the state machine shown in Figure 249. All counters and flags should be cleared after reset. When *Go* transitions from 0 to 1 all counters and flags should take their initial value. While the *Go* bit is 1, the state machine requests a read access from the dead nozzle table in DRAM provided there is enough space in its FIFO. A modulo-4 counter, *rd_count*, is used to count each of the 64-bits received in a 256-bit read access. It is incremented whenever *diu_dnc_rvalid* is asserted. When *Go* is 1, *dn_table_radr* is set to *dn_table_start_adr*. As each 64-bit value is returned, indicated by *diu_dnc_rvalid* being asserted, *dn_table_radr* is compared to *dn_table_end_adr*.

- If rd_count equals 3 and dn_table_radr equals dn_table_end_adr, then dn_table_radr is updated to dn_table_start_adr.
 - If rd_count equals 3 and dn_table_radr does not equal dn_table_end_adr, then dn_table_radr is incremented by 1.

A count is kept of the number of 64-bit values in the FIFO. When diu_dnc_rvalid is 1 data is

written to the FIFO by asserting wr_en, and fifo_contents and fifo_wr_adr are both incremented.

When fifo_contents[3:0] is greater than 0 and edu_ready is 1, dnc_hcu_ready is asserted to indicate that the DNC is ready to accept dots from the HCU. If hcu_dnc_avail is also 1 then a dotadv pulse is sent to the GenMask unit, indicating the DNC has accepted a dot from the HCU, and iru_avail is also asserted. After Go is set, a single preload pulse is sent to the GenMask unit once the FIFO contains data.

When a rd_adv pulse is received from the GenMask unit, $fifo_rd_adr[4:0]$ is then incremented to select the next 16-bit value. If $fifo_rd_adr[1:0] = 11$ then the next 64-bit value is read from the FIFO by asserting rd_en , and $fifo_contents[3:0]$ is decremented.

29.5.3.2 Dead nozzle FIFO

The dead nozzle FIFO conceptually is a 64-bit input, and 16-bit output FIFO to account for the 64-bit data transfers from the DIU, and the individual 16-bit entries in the dead nozzle table that are used in the GenMask unit. In reality, the FIFO is actually 8 entries deep and 64-bits wide (to accommodate two 256-bit accesses).

On the DRAM side of the FIFO the write address is 64-bit aligned while on the GenMask side the read address is 16-bit aligned, i.e. the upper 3 bits are input as the read address for the FIFO and the lower 2 bits are used to select 16 bits from the 64 bits (1st 16 bits read corresponds to bits 15-0, second 16 bits to bits 31-16 etc.).

29.5.3.3 GenMask unit

35

The GenMask unit generates the 6-bit *dn_mask* that is sent to the replace unit. It consists of a 10-bit delta counter and a mask register.

After *Go* is set, the GenMask unit will receive a *preload* pulse from the control unit indicating the first dead nozzle table entry is available at the output of the dead nozzle FIFO and should be loaded into the delta counter and mask register. A *rd_adv* pulse is generated so that the next dead nozzle table entry is presented at the output of the dead nozzle FIFO. The delta counter is decremented every time a *dotadv* pulse is received. When the delta counter reaches 0, it gets loaded with the current delta value output from the dead nozzle FIFO, i.e. bits 15-6, and the mask register gets loaded with mask output from the dead nozzle FIFO, i.e. bits 5-0. A *rd_adv* pulse is then generated so that the next dead nozzle table entry is presented at the output of the dead nozzle FIFO.

When the delta counter is 0 the value in the mask register is output as the *dn_mask*, otherwise the *dn_mask* is all 0s.

The GenMask unit has no knowledge of the number of dots in a line, it simply loads a counter to count the delta from one dead nozzle column to the next. Thus as described in section 29.2 on page 472 the dead nozzle table should include null identifiers if necessary so that the dead nozzle table covers the first and last nozzle column in a line.

29.5.3.4 Replace unit

15

Dead nozzle removal and ink replacement are implemented by the combinatorial logic shown in Figure 250. Dead nozzle removal is performed by bit-wise ANDing of the inverse of the *dn_mask* with the dot value.

The ink replacement mechanism has 6 ink replacement patterns, one per ink plane, programmable by the CPU. The dead nozzle mask is ANDed with the dot data to see if there are any planes where the dot is active but the corresponding nozzle is dead. The resultant value forms an enable, on a per ink basis, for the ink replacement process. If replacement is enabled for a particular ink, the values from the corresponding replacement pattern register are ORed into the dot data. The output of the ink replacement process is then filtered so that error diffusion is only allowed for the planes in which error diffusion is enabled.

The output of the ink replacement process is ORed with the resultant dot after dead nozzle removal. If the dot position does not contain a dead nozzle then the *dn_mask* will be all 0s and the dot, *hcu_dnc_data*, will be passed through unchanged.

30 29.5.4 Error Diffusion Unit

Figure 251 shows a sub-block diagram for the error diffusion unit.

29.5.4.1 Random Bit Generator

The random bit value used to arbitrarily select the direction of diffusion is generated by a maximum length 32-bit LFSR. The tap points and feedback generation are shown in Figure 252.

- The LFSR generates a new bit for each dot in a line regardless of whether the dot is dead or not, i.e shifting of the LFSR is enabled when *advdot* equals 1. The LFSR can be initialised with a 32-bit programmable seed value, *random_seed*. This seed value is loaded into the LFSR whenever a write occurs to the *RandomSeed* register. Note that the seed value must not be all 1s as this causes the LFSR to lock-up.
- 40 29.5.4.2 Advance Dot Unit

The advance dot unit is responsible for determining in a given cycle whether or not the error diffuse unit will accept a dot from the ink replacement unit or make a dot available to the fixative correct unit and on to the DWU. It therefore receives the <code>dwu_dnc_ready</code> control signal from the DWU, the <code>iru_avail</code> flag from the ink replacement unit, and generates <code>dnc_dwu_avail</code> and <code>edu_ready</code> control flags.

Only the <code>dwu_dnc_ready</code> signal needs to be checked to see if a dot can be accepted and asserts <code>edu_ready</code> to indicate this. If the error diffuse unit is ready to accept a dot and the ink replacement unit has a dot available, then a <code>advdot</code> pulse is given to shift the dot into the pipeline in the diffuse unit. Note that since the error diffusion operates on 3 dots, the advance dot unit ignores <code>dwu_dnc_ready</code> initially until 3 dots have been accepted by the diffuse unit. Similarly <code>dnc_dwu_avail</code> is not asserted until the diffuse unit contains 3 dots and the ink replacement unit has a dot available.

29.5.4.3 Diffuse Unit

5

10

15

20

25

The diffuse unit contains the combinatorial logic to implement the truth table from Table . The diffuse unit receives a dot consisting of 6 color planes (1 bit per plane) as well as an associated 6-bit dead nozzle mask value.

Error diffusion is applied to all 6 planes of the dot in parallel. Since error diffusion operates on 3 dots, the diffuse unit has a pipeline of 3 dots and their corresponding dead nozzle mask values. The first dot received is referred to as dot A, and the second as dot B, and the third as dot C. Dots are shifted along the pipeline whenever *advdot* is 1. A count is also kept of the number of dots received. It is incremented whenever *advdot* is 1, and wraps to 0 when it reaches *max_dot*. When the dot count is 0 dot C corresponds to the first dot in a line. When the dot count is 1 dot A corresponds to the last dot in a line.

In any given set of 3 dots only dot B can be defined as containing a dead nozzle(s). Dead nozzles are identified by bits set in *iru_dn_mask*. If dot B contains a dead nozzle(s), the corresponding bit(s) in dot A, dot C, the dead nozzle mask value for A, the dead nozzle mask value for C, the dot count, as well as the random bit value are input to the truth table logic and the dots A, B and C assigned accordingly. If dot B does not contain a dead nozzle then the dots are shifted along the pipeline unchanged.

30 29.5.5 Fixative Correction Unit

The fixative correction unit consists of combinatorial logic to implement fixative correction as defined in Table 203. For each output dot the DNC determines if fixative is required for the new compensated dot data word and whether fixative is activated already for that dot.

```
FixativePresent = ((FixativeMask1 | FixativeMask2) & edu_data) != 0

FixativeRequired = (FixativeRequiredMask & edu_data) != 0

It then looks up the truth table to see what action, if any, needs to be taken.
```

Table 203. Truth table for fixative correction

40

Fixative Present	Fixative	Action	Output
	required		
1	1	Output dot as is.	dnc_dwu_data = edu_data
1	О .	Clear fixative plane.	dnc_dwu_data = (edu_data) &
			~(FixativeMask1 FixativeMask2)
0	1	Attempt to add fixative.	if (FixativeMask1 & DnMask) != 0
			dnc_dwu_data = (edu_data)
			(FixativeMask2 & ~DnMask)
			else
			dnc_dwu_data = (edu_data)
			(FixativeMask1)
0	0	Output dot as is.	dnc_dwu_data = edu_data

When attempting to add fixative the DNC first tries to add it into the plane defined by *FixativeMask1*. However, if this plane is dead then it tries to add fixative by placing it into the plane defined by *FixativeMask2*. Note that if both *FixativeMask1* and *FixativeMask2* are both all 0s then the dot data will not be changed.

5 30 Dotline Writer Unit (DWU)

30.1 OVERVIEW

10

15

The Dotline Writer Unit (DWU) receives 1 dot (6 bits) of color information per cycle from the DNC. Dot data received is bundled into 256-bit words and transferred to the DRAM. The DWU (in conjunction with the LLU) implements a dot line FIFO mechanism to compensate for the physical placement of nozzles in a printhead, and provides data rate smoothing to allow for local complexities in the dot data generate pipeline.

30.2 PHYSICAL REQUIREMENT IMPOSED BY THE PRINTHEAD

The physical placement of nozzles in the printhead means that in one firing sequence of all nozzles, dots will be produced over several print lines. The printhead consists of 12 rows of nozzles, one for each color of odd and even dots. Odd and even nozzles are separated by D_2 print lines and nozzles of different colors are separated by D_1 print lines. See Figure 254 for reference. The first color to be printed is the first row of nozzles encountered by the incoming paper. In the example this is color 0 odd, although is dependent on the printhead type (see [10] for other printhead arrangments). Paper passes under printhead moving downwards.

- For example if the physical separation of each half row is 80μm equating to D₁=D₂=5 print lines at 1600dpi. This means that in one firing sequence, color 0 odd nozzles will fire on dotline L, color 0 even nozzles will fire on dotline L-D₁, color 1 odd nozzles will fire on dotline L-D₁-D₂ and so on over 6 color planes odd and even nozzles. The total number of lines fired over is given as 0+5+5.....+5= 0 + 11x5 =55. See Figure 255 for example diagram.
- It is expected that the physical spacing of the printhead nozzles will be 80μm (or 5 dot lines), although there is no dependency on nozzle spacing. The DWU is configurable to allow other line nozzle spacings.

Table 204. Relationship between Nozzle color/sense and line firing

Color	Even line e	encountered first	Odd line encountered first		
	Sense	line	sense	line	
Color 0	Even	L	even	L-5	
	Odd	L-5	odd	L	
Color 1	Even	L-10	even	L-15	
	Odd	_ L-15	odd	L-10	
Color 2	Even	L-20	even	L-25	
	Odd	L-25	odd	L-20	
Color 3	Even	L-30	even	L-35	
	Odd	L-35	odd	L-30	
Color 4	Even	L-40	even	L-45	
	Odd	L-45	odd	L-40	
Color 5	Even	L-50	even	L-55	
	Odd	L-55	odd	L-50	

30.3 LINE RATE DE-COUPLING

5

15

20

25

The DWU block is required to compensate for the physical spacing between lines of nozzles. It does this by storing dot lines in a FIFO (in DRAM) until such time as they are required by the LLU for dot data transfer to the printhead interface. Colors are stored separately because they are needed at different times by the LLU. The dot line store must store enough lines to compensate for the physical line separation of the printhead but can optionally store more lines to allow system level data rate variation between the read (printhead feed) and write sides (dot data generation pipeline) of the FIFOs.

A logical representation of the FIFOs is shown in Figure 256, where N is defined as the optional number of extra half lines in the dot line store for data rate de-coupling.

30.4 DOT LINE STORE STORAGE REQUIREMENTS

For an arbitrary page width of d dots (where d is even), the number of dots per half line is d/2. For interline spacing of D_2 and inter-color spacing of D_1 , with C colors of odd and even half lines, the number of half line storage is (C - 1) (D_2+D_1) + D1.

For N extra half line stores for each color odd and even, the storage is given by (N * C * 2). The total storage requirement is $((C - 1) (D_2+D_1) + D1 + (N * C * 2)) * d/2$ in bits.

Note that when determining the storage requirements for the dot line store, the number of dots per line is the page width and not necessarily the printhead width. The page width is often the dot margin number of dots less than the printhead width. They can be the same size for full bleed printing

For example in an A4 page a line consists of 13824 dots at 1600 dpi, or 6912 dots per half dot line. To store just enough dot lines to account for an inter-line nozzle spacing of 5 dot lines it would take 55 half dot lines for color 5 odd, 50 dot lines for color 5 even and so on, giving 55+50+45...10+5+0= 330 half dot lines in total. If it is assumed that N=4 then the storage required

to store 4 extra half lines per color is 4 x 12=48, in total giving 330+48=378 half dot lines. Each half dot line is 6912 dots, at 1 bit per dot give a total storage requirement of 6912 dots x 378 half dot lines / 8 bits = Approx 319 Kbytes. Similarly for an A3 size page with 19488 dots per line, 9744 dots per half line x 378 half dot lines / 8 = Approx 899 Kbytes.

Table 205. Storage requirement for dot line store

Page size	Nozzle	Lines required (N=0)	Storage (N=0)	Lines required	Storage (N=4)
	Spacing		Kbytes	(N=4)	Kbytes
A4	4	264	223	312	263
	5	330	278	378	319
A3	4	264	628	312	742
	5	330	785	378	899

The potential size of the dot line store makes it unfeasible to be implemented in on-chip SRAM, requiring the dot line store to be implemented in embedded DRAM. This allows a configurable dotline store where unused storage can be redistributed for use by other parts of the system.

10 30.5 Nozzle row skew

5

15

20

25

30

Due to construction limitations of the bi-lithic printhead it is possible that nozzle rows may be misaligned relative to each other. Odd and even rows, and adjacent color rows may be horizontally misaligned by up to 2 dot positions. Vertical misalignment can also occur but is compensated for in the LLU and not considered here. The DWU is required to compensate for the horizontal misalignment.

Dot data from the HCU (through the DNC) produces a dot of 6 colors all destined for the same physical location on paper. If the nozzle rows in the printhead are aligned as shown in Figure 254 then no adjustment of the dot data is needed.

A conceptual misaligned printhead is shown in Figure 257. The exact shape of the row alignment is arbitrary, although is most likely to be sloping (if sloping, it could be sloping in either direction). The DWU is required to adjust the shape of the dot streams to take account of the join between printhead ICs. The introduction of the join shape before the data is written to the DRAM means that the PHI sees a single crossover point in the data since all lines are the same length and the crossover point (since all rows are of equal length) is a vertical line - i.e. the crossover is at the same time for all even rows, and at the same time for all odd rows as shown in Figure 258.

To insert the shape of the join into the dot stream, for each line we must first insert the dots for non-printable area 1, then the printable area data (from the DNC), and then finally the dots for non-printable area 2. This can also be considered as: first produce the dots for non-printable area 1 for line n, and then a repetition of:

- produce the dots for the printable area for line n (from the DNC)
- produce the dots for the non-printable area 2 (for line n) followed by the dots of non-printable area 1 (for line n+1)

The reason for considering the problem this way is that regardless of the shape of the join, the shape of non-printable area 2 merged with the shape of non-printable area 1 will always be a

rectangle since the widths of non-printable areas 1 and 2 are identical and the lengths of each row are identical. Hence step 2 can be accomplished by simply inserting a constant number (MaxNozzleSkew) of 0 dots into the stream.

For example, if the color n even row non-printable area 1 is of length X, then the length of color n even row non-printable area 2 will be of length MaxNozzleSkew - X. The split between non-printable areas 1 and 2 is defined by the *NozzleSkew* registers.

Data from the DNC is destined for the printable area only, the DWU must generate the data destined for the non-printable areas, and insert DNC dot data correctly into the dot data stream before writing dot data to the fifos. The DWU inserts the shape of the misalignment into the dot stream by delaying dot data destined to different nozzle rows by the relative misalignment skew amount.

30.6 LOCAL BUFFERING

5

10

15

20

25

30

35

40

An embedded DRAM is expected to be of the order of 256 bits wide, which results in 27 words per half line of an A4 page, and 54 words per half line of A3. This requires 27 words x 12 half colors (6 colors odd and even) = 324 x 256-bit DRAM accesses over a dotline print time, equating to 6 bits per cycle (equal to DNC generate rate of 6 bits per cycle). Each half color is required to be double buffered, while filling one buffer the other buffer is being written to DRAM. This results in 256 bits x 2 buffers x 12 half colors i.e. 6144 bits in total.

The buffer requirement can be reduced, by using 1.5 buffering, where the DWU is filling 128 bits while the remaining 256 bits are being written to DRAM. While this reduces the required buffering locally it increases the peak bandwidth requirement to the DRAM. With 2x buffering the average and peak DRAM bandwidth requirement is the same and is 6 bits per cycle, alternatively with 1.5x buffering the average DRAM bandwidth requirement is 6 bits per cycle but the peak bandwidth requirement is 12 bits per cycle. The amount of buffering used will depend on the DRAM bandwidth available to the DWU unit.

Should the DWU fail to get the required DRAM access within the specified time, the DWU will stall the DNC data generation. The DWU will issue the stall in sufficient time for the DNC to respond and still not cause a FIFO overrun. Should the stall persist for a sufficiently long time, the PHI will be starved of data and be unable to deliver data to the printhead in time. The sizing of the dotline store FIFO and internal FIFOs should be chosen so as to prevent such a stall happening.

30.7 DOTLINE DATA IN MEMORY

The dot data shift register order in the printhead is shown in Figure 254 (the transmit order is the opposite of the shift register order). In the example the type 0 printhead IC transmit order is increasing even color data followed by decreasing odd color data. The type 1 printhead IC transmit order is decreasing odd color data followed by increasing even color data. For both printhead ICs the even data is always increasing order and odd data is always decreasing. The PHI controls which printhead IC data gets shifted to.

From this it is beneficial to store even data in increasing order in DRAM and odd data in decreasing order. While this order suits the example printhead, other printheads exist where it would be beneficial to store even data in decreasing order, and odd data in increasing order,

hence the order is configurable. The order that data is stored in memory is controlled by setting the *ColorLineSense* register.

The dot order in DRAM for increasing and decreasing sense is shown in Figure 260 and Figure 261 respectively. For each line in the dot store the order is the same (although for odd lines the numbering will be different the order will remain the same). Dot data from the DNC is always received in increasing dot number order. For increasing sense dot data is bundled into 256-bit words and written in increasing order in DRAM, word 0 first, then word 1, and so on to word N, where N is the number of words in a line.

For decreasing sense dot data is also bundled into 256-bit words, but is written to DRAM in decreasing order, i.e. word N is written first then word N-1 and so on to word 0. For both increasing and decreasing sense the data is aligned to bit 0 of a word, i.e. increasing sense always starts at bit 0, decreasing sense always finishes at bit 0.

Each half color is configured independently of any other color. The *ColorBaseAdr* register specifies the position where data for a particular dotline FIFO will begin writing to. Note that for increasing sense colors the *ColorBaseAdr* register specifies the address of the first word of first line of the fifo, whereas for decreasing sense colors the *ColorBaseAdr* register specifies the address of last word of the first line of the FIFO.

Dot data received from the DNC is bundled in 256-bit words and transferred to the DRAM. Each line of data is stored consecutively in DRAM, with each line separated by *ColorLineInc* number of words.

For each line stored in DRAM the DWU increments the line count and calculates the DRAM address for the next line to store.

This process continues until *ColorFifoSize* number of lines are stored, after which the DRAM address will wrap back to the *ColorBaseAdr* address.

As each line is written to the FIFO, the DWU increments the *FifoFillLevel* register, and as the LLU reads a line from the FIFO the *FifoFillLevel* register is decremented. The LLU indicates that it has completed reading a line by a high pulse on the *Ilu_dwu_line_rd* line.

When the number of lines stored in the FIFO is equal to the *MaxWriteAhead* value the DWU will indicate to the DNC that it is no longer able to receive data (i.e. a stall) by deasserting the *dwu_dnc_ready* signal.

The *ColorEnable* register determines which color planes should be processed, if a plane is turned off, data is ignored for that plane and no DRAM accesses for that plane are generated.

30.8 SPECIFYING DOT FIFOS

The dot line FIFOs when accessed by the LLU are specified differently than when accessed by the DWU. The DWU uses a start address and number of lines value to specify a dot FIFO, the LLU uses a start and end address for each dot FIFO. The mechanisms differ to allow more efficient implementations in each block.

As a result of limitations in the LLU the dot FIFOs must be specified contiguously and increasing in DRAM. See section 31.6 on page 504 for further information.

30.9.1 Definitions of I/O
Table 206. DWU I/O Definition

Port name	Pins	1/0	Description	
Clocks and Resets	· · · · · ·			
Pclk	1	ln	System Clock	
prst_n	1	ln	System reset, synchronous active low	
DNC Interface	L	<u> </u>		
dwu_dnc_ready	1	Out	Indicates that DWU is ready to accept data from	
			the DNC.	
dnc_dwu_avail	1	ln	Indicates valid data present on dnc_dwu_data.	
dnc_dwu_data[5:0]	6	In	Input bi-level dot data in 6 ink planes.	
LLU Interface		- I		
dwu_llu_line_wr	1	Out	DWU line write. Indicates that the DWU has	
			completed a full line write. Active high	
llfu_dwu_line_rd	1	ln	LLU line read. Indicates that the LLU has	
			completed a line read. Active high.	
PCU Interface				
pcu_dwu_sel	1	ln	Block select from the PCU. When pcu_dwu_sel is	
			high both pcu_adr and pcu_dataout are valid.	
pcu_rwn	1	ln	Common read/not-write signal from the PCU.	
pcu_adr[7:2]	6	ln	PCU address bus. Only 6 bits are required to	
			decode the address space for this block.	
pcu_dataout[31:0]	32	ln	Shared write data bus from the PCU.	
dwu_pcu_rdy	1	Out	Ready signal to the PCU. When dwu_pcu_rdy is	
			high it indicates the last cycle of the access. For a	
			write cycle this means pcu_dataout has been	
			registered by the block and for a read cycle this	
			means the data on dwu_pcu_datain is valid.	
dwu_pcu_datain[31:0]	32	Out	Read data bus to the PCU.	
DIU Interface				
dwu_diu_wreq	1	Out	DWU requests DRAM write. A write request must	
·			be accompanied by a valid write address together	
			with valid write data and a write valid.	
dwu_diu_wadr[21:5]	17	Out	Write address to DIU	
			17 bits wide (256-bit aligned word)	
diu_dwu_wack	1	ln	Acknowledge from DIU that write request has	
			been accepted and new write address can be	
			placed on dwu_diu_wadr	

dwu_diu_data[63:0]	64	Out	Data from DWU to DIU. 256-bit word transfer over
			4 cycles
			First 64-bits is bits 63:0 of 256 bit word
			Second 64-bits is bits 127:64 of 256 bit word
			Third 64-bits is bits 191:128 of 256 bit word
			Fourth 64-bits is bits 255:192 of 256 bit word
dwu_diu_wvalid	1	Out	Signal from DWU indicating that data on
			dwu_diu_data is valid.

30.9.2 DWU partition

5

30.9.3 Configuration registers

The configuration registers in the DWU are programmed via the PCU interface. Refer to section 21.8.2 on page 321 for a description of the protocol and timing diagrams for reading and writing registers in the DWU. Note that since addresses in SoPEC are byte aligned and the PCU only supports 32-bit register reads and writes, the lower 2 bits of the PCU address bus are not required to decode the address space for the DWU. When reading a register that is less than 32 bits wide zeros should be returned on the upper unused bit(s) of dwu_pcu_data. Table 207 lists the configuration registers in the DWU.

10 Table 207. DWU registers description

Address DWU_base+	Register	#bits	Reset	Description
Control Registers	S			
0x00	Reset	1	0x1	Active low synchronous reset, self de- activating. A write to this register will cause a DWU block reset.
0x04	Go	1	0x0	Active high bit indicating the DWU is programmed and ready to use. A low to high transition will cause DWU block internal states to reset (configuration registers are not reset).
Dot Line Store C	onfiguration			
0x08 – 0x34	ColorBaseA dr[11:0][21: 5]	12x17	0x000 00	Specifies the base address (in words) in memory where data from a particular half color (N) will be placed. For increasing sense colors the <i>ColorBase-Adr</i> register specifies the address of the first word of first line of the fifo, whereas for decreasing sense colors the <i>ColorBaseAdr</i> register specifies the

			address of last word of the first line of
i 			the fifo.
0x38 - 0x64	ColorFifoSiz 12x8	0x00	Indicates the number of lines in the
	e[11:0]		FIFO before the line increment will wrap
			around in memory.
			Bus 0,1 - Even, Odd line color 0
			Bus 2,3 - Even, Odd line color 1
			Bus 4,5 - Even, Odd line color 2
			Bus 6,7 - Even, Odd line color 3
			Bus 8,9 - Even, Odd line color 4
			Bus 10,11 - Even, Odd line color 5
0x68	ColorLineSe 2	0x2	Specifies whether data written to DRAM
	nse		for this half color is increasing or
			decreasing sense
			0 - Decreasing sense
1			1 - Increasing sense
			Bit 0 Defines even color sense,
			Bit 1 Defines odd color sense.
0x6C	ColorEnable 6	0x3F	Indicates whether a particular color is
			active or not.
			When inactive no data is written to
İ			DRAM for that color.
			0 - Color off
			1 - Color on
			One bit per color, bit 0 is Color 0 and so
			on.
0x70	MaxWriteAh8	0x00	Specifies the maximum number of lines
	ead		that the DWU can be ahead of the LLU
0x74	LineSize 16	0x000 0	Indicates the number of dots per line
			produced by the DWU.
0x78	MaxNozzle 4	0x0	Specifies the number of dot-pairs the
	Skew		DWU needs to generate to flush the
			data skew buffers. Corresponds to the
			non-printable area of the printhead.
0x7C - 0xA8	NozzleSkew 12x4	0x0	Specifies the relative skew of dot data
			nozzle rows in the printhead. Valid
			range is 0 (no skew) through to 12.
			Units represent dot-pairs, a skew of 1
			for a row represents two dots on the
L		1	<u> </u>

				page.
				Bus 0,1 - Even, Odd line color 0
				Bus 2,3 - Even, Odd line color 1
				Bus 4,5 - Even, Odd line color 2
				Bus 6,7 - Even, Odd line color 3
				Bus 8,9 - Even, Odd line color 4
				Bus 10,11 - Even, Odd line color 5
0xAC	ColorLineIn	8	0x00	Specifies the number of words (256-bit
	c			words) per dot line - 1.
Working Registe	ers		· 	
0xB0	LineDotCnt	16	0x000 0	Indicates the number of remaining dots
				in the current line. (Read Only)
0xB4	FifoFillLevel	8	0x00	Number of lines in the FIFO, written to
				but not read. (Read Only)

A low to high transition of the *Go* register causes the internal states of the DWU to be reset. All configuration registers will remain the same. The block indicates the transition to other blocks via the *dwu_go_pulse* signal.

30.9.4 Data skew

10

15

20

The data skew block inserts the shape of the printhead join into the dot data stream by delaying dot data by the relative nozzle skew amount (given by nozzle_skew). It generates zero fill data introduced introduced into the dot data stream to achieve the relative skew (and also to flush dot data from the delay registers).

The data skew block consists of 12 12-bit shift registers, one per color odd and even. The shift registers are in groups of 6, one group for even colors, and one for odd colors. Each time a valid data word is received from the DNC the dot data is shifted into either the odd or even group of shift registers. The *odd_even_sel* register determines which group of shift registers are valid for that cycle and alternates for each new valid data word. When a valid word is received for a group of shift registers, the shift register is shifted by one location with the new data word shifted into the registers (the top word in the register will be discarded).

When the dot counter determines that the data skew block should zero fill (zero_fill), the data skew block will shift zero dot data into the shift registers until the line has completed. During this time the DNC will be stalled by the de-assertion of the dwu_dnc_ready signal.

The data skew block selects dot data from the shift registers and is passed to the buffer address generator block. The data bits selected is determined by the configured index values in the *NozzleSkew* registers.

```
else
                   dot_data_in = dnc_dwu_data
                 // the data delay buffers
                 if (dwu go pulse ==1) then
5
                   data delay[1:0][11:0][5:0]
                                                 = 0
                                                                  // reset all
                 delay buffer odd=1,even=0
                   odd even sel
                 elsif (data_valid == 1) then {
                   odd_even_sel = ~odd_even_sel
10
                   // update the odd/even buffers, with shift
                   data_delay[odd_even_sel][11:1][5:0]=
                 data delay[odd even sel][10:0][5:0] // shift data
                   data delay[odd even sel][0][5:0]
                                                               dot data in[5:0]
                 // shift in new data
15
                   // select the correct output data
                   for (i=0;i<6;i++) {
                      // skew selector
                                                        {i,odd even sel}
                      skew
                                      nozzle skew[ ·
                                                                              ]
                 // temporary variable
20
                      // data select array, include data delay and input dot
                 data
                                              {data_delay[odd_even_sel][11:0],
                      data_select[12:0]
                 dot data in}
                      // mux output the data word to next block (13 to 1 mux)
25
                      dot data[i] = data select[skew][i]
                      }
                   }
```

30.9.5 Fifo fill level

- The DWU keeps a running total of the number of lines in the dot store FIFO. Each time the DWU writes a line to DRAM (determined by the DIU interface subblock and signalled via line_wr) it increments the filllevel and signals the line increment to the LLU (pulse on dwu_llu_line_wr). Conversely if it receives an active llu_dwu_line_rd pulse from the LLU, the filllevel is decremented. If the filllevel increases to the programmed max level (max_write_ahead) then the DWU stalls and indicates back to the DNC by de-asserting the dwu_dnc_ready signal. If one or more of the DIU buffers fill, the DIU interface signals the fill level logic via the buf_full signal which in turn causes the DWU to de-assert the dwu_dnc_ready signal to stall the DNC. The buf_full signals will remain active until the DIU services a pending request from the full buffer, reducing the buffer level.
- When the dot counter block detects that it needs to insert zero fill dots (zero_fill equals 1) the DWU will stall the DNC while the zero dots are being generated (by de-asserting dwu_dnc_ready), but will allow the data skew block to generate zero fill data (the dwu_ready signal).

```
dwu_dnc_ready = ~((buf_full== 1) OR (filllevel ==
max_write_ahead ) OR (zero_fill == 1))
dwu_ready = ~((buf_full== 1) OR (filllevel ==
max_write_ahead ))
```

The DWU does not increment the fill level until a complete line of dot data is in DRAM not just a complete line received from the DNC. This ensures that the LLU cannot start reading a partial line from DRAM before the DWU has finished writing the line.

The fill level is reset to zero each time a new page is started, on receiving a pulse via the dwu_go_pulse signal.

The line fifo fill level can be read by the CPU via the PCU at any time by accessing the FifoFillLevel register.

30.9.6 Buffer address generator

15

20

25

30

30.9.6.1 Buffer address generator description

The buffer address generator subblock is responsible for accepting data from the data skew block and writing it to the DIU buffers in the correct order.

The buffer address and active bit-write for a particular dot data write is calculated by the buffer address generator based on the dot count of the current line, programmed sense of the color and the line size.

All configuration registers should be programmed while the *Go* bit is set to zero, once complete the block can be enabled by setting the *Go* bit to one. The transition from zero to one will cause the internal states to reset.

If the *color_line_sense* signal for a color is one (i.e. increasing) then the bit-write generation is straight forward as dot data is aligned with a 256-bit boundary. So for the first dot in that color, the bit 0 of the *wr_bit* bus will be active (in buffer word 0), for the second dot bit 1 is active and so on to the 255th dot where bit 63 is active (in buffer word 3). This is repeated for all 256-bit words until the final word where only a partial number of bits are written before the word is transferred to DRAM.

If *color_line_sense* signal for a color is zero (i.e. decreasing) the bit-write generation for that color is adjusted by an offset calculated from the pre-programmed line length (*line_size*). The offset adjusts the bit write to allow the line to finish on a 256-bit boundary. For example if the line length was 400, for the first dot received bit 7 (line length is halved because of odd/even lines of color) of the *wr_bit* is active (buffer word 3), the second bit 6 (buffer word 3), to the 200th dot of data with bit 0 of *wr_bit* active (buffer word 0).

30.9.6.2 Bit-write decode

- The buffer address generator contains 2 instances of the bit-write decode, one configured for odd dot data the other for even. The counter (either up or down counter) used to generate the addresses is selected by the *color_line_sense* signal. Each block determines if it is active on this cycle by comparing its configured type with the current dot count address and the *data_active* signal.
- The *wr_bit* bus is a direct decoding of the lower 6 count bits (*count[6:1]*), and the DIU buffer address is the remaining higher bits of the counter (*count[10:7]*).

The signal generation is given as follows:

30.9.6.3 Up counter generator

The up counter increments for each new dot and is used to determine the write position of the dot in the DIU buffers for increasing sense data. At the end of each line of dot data (as indicated by line_fin), the counter is rounded up to the nearest 256-bit word boundary. This causes the DIU buffers to be flushed to DRAM including any partially filled 256-bit words. The counter is reset to zero if the dwu_go_pulse is one.

20

40

```
// Up-Counter Logic
if (dwu_go_pulse == 1) then {
    up_cnt[10:0] = 0
    elsif (line_fin == 1 ) then

// round up
    if (up_cnt[8:1] != 0)
        up_cnt[10:9]++
    else
        up_cnt[10:9]

// bit-selector
    up_cnt[7:0]=0
elsif (data_valid == 1) then
    up_cnt[7:0]++
```

35 30.9.6.4 Down counter generator

The down counter logic decrements for each new dot and is used to determine the write position of the dot in the DUI buffers for decreasing sense data. When the <code>dwu_go_pulse</code> bit is one the lower bits (i.e. 8 to 0) of the counter are reset to line size value (<code>line_size</code>), and the higher bits to zero. The bits used to determine the bit-write values and 64-bit word addresses in the DIU buffers begin at line size and count down to zero. The remaining higher bits are used to determine the DIU buffer 256-bit address and buffer fill level, begin at zero and count up. The counter is active when valid dot data is present, i.e. <code>data_valid</code> equals 1.

When the end of line is detected (*line_fin* equals 1) the counter is rounded to the next 256-bit word, and the lower bits are reset to the line size value.

```
//Down-Counter Logic
                 if (dwu_go_pulse == 1) then
                   dn_cnt[8:0] = line_size[8:0]
                   dn cnt[10:9] = 0
 5
                 elsif (line_fin == 1 ) then
                   // perform rounding up
                   if (dn_cnt[8:1] != 0)
                      dn_cnt[10:9]++
                   else
10
                      dn cnt[10:9]
                   // bit-select is reset
                   dn_cnt[8:0] = line_size[8:0]
                                                 // bit select bits
                 elsif (data valid == 1) then
                   dn cnt[8:0] --
15
                   dn cnt[10:9]++
```

30.9.6.5 Dot counter

20

35

40

The dot counter simply counts each active dot received from the data skew block. It sets the counter to *line_size* and decrements each time a valid dot is received. When the count equals zero the *line_fin* signal is pulsed and the counter is reset to *line_size*.

When the count is less than the <code>max_nozzle_skew * 2</code> value the dot counter indicates to the data skew block to zero fill the remainder of the line (via the <code>zero_fill</code> signal). Note that the <code>max_nozzle_skew</code> units are dot-pairs as opposed to dots, hence the by 2 multiplication for comparison with the dot counter.

The counter is reset to *line_size* when *dwu_go_pulse* is 1.

30.9.7 DIU buffer

The DIU buffer is a 64 bit x 8 word dual port register array with bit write capability. The buffer could be implemented with flip-flops should it prove more efficient.

30.9.8 DIU interface

30 30.9.8.1 DIU interface general description

The DIU interface determines when a buffer needs a data word to be transferred to DRAM. It generates the DRAM address based on the dot line position, the color base address and the other programmed parameters. A write request is made to DRAM and when acknowledged a 256-bit data word is transferred. The interface determines if further words need to be transferred and repeats the transfer process.

If the FIFO in DRAM has reached its maximum level, or one of the buffers has temporarily filled, the DWU will stall data generation from the DNC.

A similar process is repeated for each line until the end of page is reached. At the end of a page the CPU is required to reset the internal state of the block before the next page can be printed. A low to high transition of the *Go* register will cause the internal block reset, which causes all registers in the block to reset with the exception of the configuration registers. The transition is indicated to subblocks by a pulse on *dwu_go_pulse* signal.

30.9.8.2 Interface controller

5

10

25

30

35

40

The interface controller state machine waits in *Idle* state until an active request is indicated by the read pointer (via the *req_active* signal). When an active request is received the machine proceeds to the *ColorSelect* state to determine which buffers need a data transfer. In the *ColorSelect* state it cycles through each color and determines if the color is enabled (and consequently the buffer needs servicing), if enabled it jumps to the *Request* state, otherwise the *color_cnt* is incremented and the next color is checked.

In the Request state the machine issues a write request to the DIU and waits in the Request state until the write request is acknowledged by the DIU (diu_dwu_wack). Once an acknowledge is received the state machine clocks through 4 cycles transferring 64-bit data words each cycle and incrementing the corresponding buffer read address. After transferring the data to the DIU the machine returns to the ColorSelect state to determine if further buffers need servicing. On the transition the controller indicates to the address generator (adr_update) to update the address for that selected color.

If all colors are transferred (*color_cnt* equal to 6) the state machine returns to *Idle*, updating the last word flags (*group_fin*) and request logic (*req_update*).

The dwu_diu_wvalid signal is a delayed version of the buf_rd_en signal to allow for pipeline delays between data leaving the buffer and being clocked through to the DIU block.

The state machine will return from any state to Idle if the reset or the dwu_go_pulse is 1.

20 30.9.8.3 Address generator

The address generator block maintains 12 pointers (*color_adr[11:0]*) to DRAM corresponding to current write address in the dot line store for each half color. When a DRAM transfer occurs the address pointer is used first and then updated for the next transfer for that color. The pointer used is selected by the *req_sel* bus, and the pointer update is initiated by the *adr_update* signal from the interface controller.

The pointer update is dependent on the sense of the color of that pointer, the pointer position in a line and the line position in the FIFO. The programming of the *color_base_adr* needs to be adjusted depending of the sense of the colors. For increasing sense colors the *color_base_adr* specifies the address of the first word of first line of the fifo, whereas for decreasing sense colors the *color_base_adr* specifies the address of last word of the first line of the FIFO.

For increasing colors, the initialization value (i.e. when <code>dwu_go_pulse</code> is 1) is the <code>color_base_adr</code>. For each word that is written to DRAM the pointer is incremented. If the word is the last word in a line (as indicated by <code>last_wd</code> from that read pointers) the pointer is also incremented. If the word is the last word in a line, and the line is the last line in the FIFO (indicated by <code>fifo_end</code> from the line counter) the pointer is reset to <code>color_base_adr</code>.

In the case of decreasing sense colors, the initialization value (i.e. when dwu_go_pulse is 1) is the color_base_adr. For each line of decreasing sense color data the pointer starts at the line end and decrements to the line start. For each word that is written to DRAM the pointer is decremented. If the word is the last word in a line the pointer is incremented by color_line_inc * 2 + 1. One line length to account for the line of data just written, and another line length for the next line to be

written. If the word is the last word in a line, and the line is the last line in the FIFO the pointer is reset to the initialization value (i.e. *color_base_adr*).

The address is calculated as follows:

```
5
                 if (dwu_go_pulse == 1) then
                   color adr[11:0] = color base adr[11:0] [21:5]
                 elsif (adr update == 1) then {
                   // determine the color
                   color = req sel[3:0]
10
                   // line end and fifo wrap
                   if ((fifo_end[color] == 1) AND (last_wd == 1)) then {
                      // line end and fifo wrap
                      color_adr[color] = color_base_adr[color][21:5]
                      }
15
                   elsif ( last_wd == 1) then {
                      // just a line end no fifo wrap
                      if (color_line_sense[color % 2]
                                                                1)
                                                                             //
                 increasing sense
                        color adr[color] ++
20
                                                                  // decreasing
                      else
                 sense
                        color_adr[color]
                                                   color_adr[color]
                 color_line_inc * 2) + 1
                      }
25
                    else {
                      // regular word write
                      if (color line sense[color %
                                                                     then
                                                                              //
                                                       2]
                                                                1)
                  increasing sense
                        color adr[color]++
30
                      else
                                                          // decreasing sense
                        color_adr[color] --
                      }
                    }
                 // select the correct address, for this transfer
35
                 dwu diu wadr = color adr[req sel]
```

30.9.8.4 Line count

40

The line counter logic counts the number of dot data lines stored in DRAM for each color. A separate pointer is maintained for each color. A line pointer is updated each time the final word of a line is transferred to DRAM. This is determined by a combination of adr_update and last_wd signals. The pointer to update is indicated by the req_sel bus.

When an update occurs to a pointer it is compared to zero, if it is non-zero the count is decremented, otherwise the counter is reset to *color_fifo_size*. If a counter is zero the *fifo_end* signals is set high to indicates to the address generator block that the line is the last line of this colors fifo.

If the dwu_go_pulse signal is one the counters are reset to color_fifo_size.

```
if (dwu_go pulse == 1) then
                    line_cnt[11:0] = color_fifo_size[11:0]
 5
                 elsif ((adr update == 1) AND (last wd == 1)) then {
                   // determine the pointer to operate on
                   color = req sel[3:0]
                   // update the pointer
                   if (line cnt[color] == 0) then
10
                      line_cnt[color] = color fifo size[color]
                   else
                      line_cnt[i] --
                    }
                 // count is zero its the last line of fifo
15
                 for(i=0 ;i <12;i++){
                    fifo_end[i] = (line_cnt[i] == 0)
```

30.9.8.5 Read Pointer

20

25

The read pointer logic maintains the buffer read address pointers. The read pointer is used to determine which 64-bit words to read from the buffer for transfer to DRAM.

The read pointer logic compares the read and write pointers of each DIU buffer to determine which buffers require data to be transferred to DRAM, and which buffers are full (the *buf_full* signal).

- Buffers are grouped into odd and even buffers groups. If an odd buffer requires DRAM access the odd_pend signals will be active, if an even buffer requires DRAM access the even_pend signals will be active. If both odd and even buffers require DRAM access at exactly the same time, the even buffers will get serviced first. If a group of odd buffers are being serviced and an even buffer becomes pending, the odd group of buffers will be completed before the starting the even group, and vice versa.
- 30 If any buffer requires a DRAM transfer, the logic will indicate to the interface controller via the req_active signal, with the odd_even_sel signal determining which group of buffers get serviced. The interface controller will check the color_enable signal and issue DRAM transfers for all enabled colors in a group. When the transfers are complete it tells the read pointer logic to update the requests pending via req_update signal.
- The *req_sel[3:0]* signal tells the address generator which buffer is being serviced, it is constructed from the *odd_even_sel* signal and the *color_cnt[2:0]* bus from the interface controller. When data is being transferred to DRAM the word pointer and read pointer for the corresponding buffer are updated. The *req_sel* determines which pointer should be incremented.

```
// determine if request is active odd
                 if ( wr_adr[1][3:2] != rd_adr[1][3:2] )
                   even pend = 1
                 else
 5
                   even pend = 0
                 // determine if any buffer is full
                 if ((wr_adr[0][3:0] - rd_adr[0][3:0]) > 7)OR((wr_adr[1][3:0]
                 - rd adr[1][3:0]) > 7)) then
                   buf full = 1
10
                 // fixed servicing order, only update when controller
                 dictates so
                 if (req update == 1) then {
                   if (even pend == 1) then
                                                   // even always first
                     odd even sel = 0
15
                      req active
                   elsif (odd pend == 1 ) then
                                                   // then check odd
                      odd even_sel = 0
                      req active
                                                    // nothing active
20
                      odd even sel = 0
                      req active
                   }
                 // selected requestor
                 req sel[3:0]
                               = {color cnt[2:0] , odd even sel}
                                                                            //
25
                 concatentation
```

The read address pointer logic consists of 2 2-bit counters and a word select pointer. The pointers are reset when dwu_go_pulse is one. The word pointer (word_ptr) is common to all buffers and is used to read out the 64-bit words from the DIU buffer. It is incremented when buf_rd_en is active. When a group of buffers are updated the state machine increments the read pointer

(rd_ptr[odd_even_sel]) via the group_fin signal. A concatenation of the read pointer and the word pointer are use to construct the buffer read address. The read pointers are not reset at the end of each line.

```
// determine which pointer to update
                 if (dwu_go_pulse == 1) then
35
                   rd ptr[1:0] = 0
                   word ptr
                 elsif (buf_rd_en == 1) then {
                                                      // word pointer update
                   word ptr++
                 elsif (group fin == 1) then
40
                   rd_ptr[odd_even_sel]++
                                                           // update the read
                 pointer
                 // create the address from the pointer, and word reader
                 rd adr[odd even sel] = {rd ptr[odd even sel], word ptr}
                                                                             11
                 concatenation
```

The read pointer block determines if the word being read from the DIU buffers is the last word of a line. The buffer address generator indicate the last dot is being written into the buffers via the *line_fin* signal. When received the logic marks the 256-bit word in the buffers as the last word. When the last word is read from the DIU buffer and transferred to DRAM, the flag for that word is reflected to the address generator.

```
// line end set the flags
                 if (dwu_go_pulse == 1) then
                   last flag[1:0] [1:0] = 0
                 elsif (line_fin == 1 ) then
10
                   // determines the current 256-bit word even been written
                   last_flag[0][wr_adr[0][2]] = 1
                                                     // even group flag
                   // determines the current 256-bit word odd been written to
                   last_flag[1][wr_adr[1][2]] = 1
                                                     // odd group flag
15
                 // last word reflection to address generator
                 last wd = last flag[odd even sel][rd ptr[reg sel][0]]
                 // clear the flag
                 if (group fin == 1 ) then
                   last_flag[odd_even_sel][rd_ptr[req_sel][0]] = 0
20
```

When a complete line has been written into the DIU buffers (but has not yet been transferred to DRAM), the buffer address generator block will pulse the *line_fin* signal. The DWU must wait until all enabled buffers are transferred to DRAM before signaling the LLU that a complete line is available in the dot line store (*dwu_llu_line_wr* signal). When the *line_fin* is received all buffers will require transfer to DRAM. Due to the arbitration, the even group will get serviced first then the odd. As a result the line finish pulse to the LLU is generated from the *last_flag* of the odd group.

```
// must be odd,odd group transfer complete and the last word
dwu_llu_line_wr = odd_even_sel AND group_fin AND last_wd
Line Loader Unit (LLU)
```

31.1 OVERVIEW

31

5

25

30

40

The Line Loader Unit (LLU) reads dot data from the line buffers in DRAM and structures the data into even and odd dot channels destined for the same print time. The blocks of dot data are transferred to the PHI and then to the printhead. Figure 267 shows a high level data flow diagram of the LLU in context.

35 31.2 PHYSICAL REQUIREMENT IMPOSED BY THE PRINTHEAD

The DWU re-orders dot data into 12 separate dot data line FIFOs in the DRAM. Each FIFO corresponds to 6 colors of odd and even data. The LLU reads the dot data line FIFOs and sends the data to the printhead interface. The LLU decides when data should be read from the dot data line FIFOs to correspond with the time that the particular nozzle on the printhead is passing the current line. The interaction of the DWU and LLU with the dot line FIFOs compensates for the physical spread of nozzles firing over several lines at once. For further explanation see Section 30 Dotline Writer Unit (DWU) and Section 32 PrintHead Interface (PHI). Figure 268 shows the

physical relationship of nozzle rows and the line time the LLU starts reading from the dot line store.

Within each line of dot data the LLU is required to generate an even and odd dot data stream to the PHI block. Figure 269 shows the even and dot streams as they would map to an example bilithic printhead. The PHI block determines which stream should be directed to which printhead IC.

31.3 DOT GENERATE AND TRANSMIT ORDER

The structure of the printhead ICs dictate the dot transmit order to each printhead IC. The LLU reads data from the dot line FIFO, generates an even and odd dot stream which is then re-ordered (in the PHI) into the transmit order for transfer to the printhead.

- The DWU separates dot data into even and odd half lines for each color and stores them in DRAM. It can store odd or even dot data in increasing or decreasing order in DRAM. The order is programmable but for descriptive purposes assume even in increasing order and odd in decreasing order. The dot order structure in DRAM is shown in Figure 261.
- The LLU contains 2 dot generator units. Each dot generator reads dot data from DRAM and
 generates a stream of odd or even dots. The dot order may be increasing or decreasing
 depending on how the DWU was programmed to write data to DRAM. An example of the even
 and odd dot data streams to DRAM is shown in Figure 270. In the example the odd dot generator
 is configured to produce odd dot data in decreasing order and the even dot generator produces
 dot data in increasing order.
- The PHI block accepts the even and odd dot data streams and reconstructs the streams into transmit order to the printhead.

The LLU line size refers to the page width in dots and not necessarily the printhead width. The page width is often the dot margin number of dots less than the printhead width. They can be the same size for full bleed printing.

25 31.4 LLU START-UP

5

At the start of a page the LLU must wait for the dot line store in DRAM to fill to a configured level (given by FifoReadThreshold) before starting to read dot data. Once the LLU starts processing dot data for a page it must continue until the end of a page, the DWU (and other PEP blocks in the pipeline) must ensure there is always data in the dot line store for the LLU to read, otherwise the

- 30 LLU will stall, causing the PHI to stall and potentially generate a print error. The FifoReadThreshold should be chosen to allow for data rate mismatches between the DWU write side and the LLU read side of the dot line FIFO. The LLU will not generate any dot data until FifoReadThreshold level in the dot line FIFO is reached.
- Once the *FifoReadThreshold* is reached the LLU begins page processing, the *FifoReadThreshold* is ignored from then on.

When the LLU begins page processing it produces dot data for all colors (although some dot data color may be null data). The LLU compares the line count of the current page, when the line count exceeds the *ColorRelLine* configured value for a particular color the LLU will start reading from that colors FIFO in DRAM. For colors that have not exceeded the *ColorRelLine* value the LLU will

generate null data (zero data) and not read from DRAM for that color. *ColorRelLine[N]* specifies the number of lines separating the Nth half color and the first half color to print on that page. For the example printhead shown in Figure 268, color 0 odd will start at line 0, the remaining colors will all have null data. Color 0 odd will continue with real data until line 5, when color 0 odd and even will contain real data the remaining colors will contain null data. At line 10, color 0 odd and even and color 1 odd will contain real data, with remaining colors containing null data. Every 5 lines a new half color will contain real data and the remaining half colors null data until line 55, when all colors will contain real data. In the example *ColorRelLine[0]* =5, *ColorRelLine[1]* =0, *ColorRelLine[2]* =15, *ColorRelLine[3]* =10 .. etc.

It is possible to turn off any one of the color planes of data (via the *ColorEnable* register), in such cases the LLU will generate zeroed dot data information to the PHI as normal but will not read data from the DRAM.

31.4.1 LLU bandwidth requirements

5

15

20

25

30

35

40

address pointers.

The LLU is required to generate data for feeding to the printhead interface, the rate required is dependent on the printhead construction and on the line rate configured. The maximum data rate the LLU can produce is 12 bits of dot data per cycle, but the PHI consumes at 12 bits every 2 *pclk* cycles out of 3, i.e. 8 bits per *pclk* cycle. Therefore the DRAM bandwidth requirement for a double buffered LLU is 8 bits per cycle on average. If 1.5 buffering is used then the peak bandwidth requirement is doubled to 16 bits per cycle but the average remains at 8 bits per cycle. Note that while the LLU and PHI could produce data at the 8 bits per cycle rate, the DWU can only produce data at 6 bits per cycle rate.

31.5 VERTICAL ROW SKEW

Due to construction limitations of the bi-lithic printhead it is possible that nozzle rows may be misaligned relative to each other. Odd and even rows, and adjacent color rows may be horizontally misaligned by up to 2 dot positions. Vertical misalignment can also occur between both printhead ICs used to construct the printhead. The DWU compensates for the horizontal misalignment (see Section 30.5), and the LLU compensates for the vertical misalignment. For each color odd and even the LLU maintains 2 pointers into DRAM, one for feeding printhead A (CurrentPtrA) and other for feeding printhead B (CurrentPtrB). Both pointers are updated and incremented in exactly the same way, but differ in their initial value programming. They differ by vertical skew number of lines, but point to the same relative position within a line. At the start of a line the LLU reads from the FIFO using CurrentPtrA until the join point between the printhead ICs is reached (specified by JoinPoint), after which the LLU reads from DRAM using CurrentPtrB. If the JoinPoint coincides with a 256-bit word boundary, the swap over from pointer A to pointer B is straightforward. If the JoinPoint is not on a 256-bit word boundary, the LLU must read the 256-bit word of data from CurrentPtrA location, generate the dot data up to the join point and then read the 256-bit word of data from CurrentPtrB location and generate dot data from the join point to the word end. This means that if the JoinPoint is not on a 256-bit boundary then the LLU is required to perform an extra read from DRAM at the join point and not increment the

31.5.1 Dot line FIFO initialization

For each dot line FIFO there are 2 pointers reading from it, each skewed by a number of dot lines in relation to the other (the skew amount could be positive or negative). Determining the exact number of valid lines in the dot line store is complicated by two pointers reading from different positions in the FIFO. It is convenient to remove the problem by pre-zeroing the dot line FIFOs effectively removing the need to determine exact data validity. The dot FIFOs can be initialized in a number of ways, including

- the CPU writing 0s,
- the LBD/SFU writing a set of 0 lines (16 bits per cycle),
- 10 the HCU/DNC/DWU being programmed to produce 0 data

31.6 SPECIFYING DOT FIFOS

The dot line FIFOs when accessed by the LLU are specified differently than when accessed by the DWU. The DWU uses a start address and number of lines value to specify a dot FIFO, the LLU uses a start and end address for each dot FIFO. The mechanisms differ to allow more efficient implementations in each block.

The start address for each half color N is specified by the *ColorBaseAdr[N]* registers and the end address (actually the end address plus 1) is specified by the *ColorBaseAdr[N+1]*. Note there are 12 colors in total, 0 to 11, the *ColorBaseAdr[12]* register specifies the end of the color 11 dot FIFO and not the start of a new dot FIFO. As a result the dot FIFOs must be specified contiguously and increasing in DRAM.

31.7 IMPLEMENTATION

31.7.1 LLU partition

31.7.2 Definitions of I/O

Table 208, LLU I/O definition

25

15

20

5

Port name	Pins	1/0	Description
Clocks and Resets			
Pclk	1	ln	System clock
prst_n	1	ln	System reset, synchronous active low
PHI Interface	L		
llu_phi_data[1:0][5:0]	2x6	Out	Dot Data from LLU to the PHI, each bit is a
			color plane 5 downto 0.
			Bus 0 - Even dot data stream
			Bus 1 - Odd dot data stream
			Data is active when corresponding bit is active
			in <i>Ilu_phi_avail</i> bus
phi_llu_ready[1:0]	2	In	Indicates that PHI is ready to accept data from
			the LLU
			0 - Even dot data stream

			1 - Odd dot data stream
llu_phi_avail[1:0]	2	Out	Indicates valid data present on corresponding
			llu_phi_data.
			0 - Even dot data stream
	E		1 - Odd dot data stream
DIU Interface			
llu_diu_rreq	1	Out	LLU requests DRAM read. A read request must
			be accompanied by a valid read address.
llu_diu_radr[21:5]	17	Out	Read address to DIU
			17 bits wide (256-bit aligned word).
diu_llu_rack	1	ln	Acknowledge from DIU that read request has
			been accepted and new read address can be
			placed on <i>llu_diu_radr</i>
diu_data[63:0]	64	ln	Data from DIU to LLU. Each access is 256-bits
			received over 4 clock cycles
			First 64-bits is bits 63:0 of 256 bit word
			Second 64-bits is bits 127:64 of 256 bit word
			Third 64-bits is bits 191:128 of 256 bit word
			Fourth 64-bits is bits 255:192 of 256 bit word
diu_llu_rvalid	1	In	Signal from DIU telling LLU that valid read data
			is on the <i>diu_data</i> bus
DWU Interface		<u></u>	
dwu_llu_line_wr	1	ln	DWU line write. Indicates that the DWU has
			completed a full line write. Active high
llu_dwu_line_rd	1	Out	LLU line read. Indicates that the LLU has
			completed a line read. Active high.
PCU Interface			
pcu_llu_sel	1	In	Block select from the PCU. When pcu_llu_sel is
			high both <i>pcu_adr</i> and <i>pcu_dataout</i> are valid.
pcu_rwn	1	In	Common read/not-write signal from the PCU.
pcu_adr[7:2]	6	In	PCU address bus. Only 6 bits are required to
			decode the address space for this block.
pcu_dataout[31:0]	32	In	Shared write data bus from the PCU.
llu_pcu_rdy	1	Out	Ready signal to the PCU. When <code>llu_pcu_rdy</code> is
			high it indicates the last cycle of the access. For
			a write cycle this means pcu_dataout has been
			registered by the block and for a read cycle this
			means the data on <i>llu_pcu_datain</i> is valid.
llu_pcu_datain[31:0]	32	Out	Read data bus to the PCU.

31.7.3 Configuration registers

The configuration registers in the LLU are programmed via the PCU interface. Refer to section 21.8.2 on page 321 for a description of the protocol and timing diagrams for reading and writing registers in the LLU. Note that since addresses in SoPEC are byte aligned and the PCU only supports 32-bit register reads and writes, the lower 2 bits of the PCU address bus are not required to decode the address space for the LLU. When reading a register that is less than 32 bits wide zeros should be returned on the upper unused bit(s) of *llu_pcu_datain*. Table 209 lists the configuration registers in the LLU.

Table 209. LLU registers description

10

5

Address LLU_base +	Register	#bits	Reset	Description					
Control Registers									
0x00	Reset	1	0x1	Active low synchronous reset, self de-					
				activating. A write to this register will					
	·			cause a LLU block reset.					
0x04	Go	1	0x0	Active high bit indicating the LLU is					
				programmed and ready to use. A low to					
				high transition will cause LLU block					
				internal states to reset.					
Configuration	n	<u></u>	<u> </u>						
0x08 - 0x38	ColorBaseAdr[12:0][13x17	0x000 00	Specifies the base address (in words) in					
	21:5]			memory where data from a particular					
				half color (N) will be placed.					
				Also specifies the end address + 1 (256-					
				bit words) in memory where fifo data for					
				a particular half color ends. For color N					
				the start address is ColorBaseAdr[N]					
				and the end address +1 is ColorBase-					
				Adr[N+1]					
0x3C	ColorEnable	6	0x3F	Indicates whether a particular color is					
	·			active or not.					
				When inactive no data is written to					
				DRAM for that color.					
				0 - Color off					
				1 - Color on					
				One bit per color, bit 0 is Color 0 and so					
				on.					
0x40	LineSize	16	0x000 0	Indicates the number of dots per line.					

0x44	FifoReadThreshold	8	0x00	Specifies the number of lines that should
				be in the FIFO before the LLU starts
				reading.
0x48 - 0x74	ColorRelLine[11:0]	12x8	0x00	Specifies the relative number of lines to
				wait from the first before starting to read
				dot data from the corresponding dot data
				FIFO
				Bus 0,1 - Even, Odd line color 0

			<u></u>	Working registers

Working Registers						
0xF0	FifoFillLevel	8	0x00	Number of lines in the dot line FIFO, line		
				written in but not read out. (Read Only)		

A low to high transition of the *Go* register causes the internal states of the LLU to be reset. All configuration registers will remain the same. The block indicates the transition to other blocks via the *llu_go_pulse* signal.

31.7.4 Dot generator

The dot generator block is responsible for reading dot data from the DIU buffers and sending the dot data in the correct order to the PHI block. The dot generator waits for *llu_en* signal from the fifo fill level block, once active it starts reading data from the 6 DIU buffers and generating dot data for feeding to the PHI.

In the LLU there are two instances of the dot generator, one generating odd data and the other generating even data.

At any time the ready bit from the PHI could be de-asserted, if this happens the dot generator will stop generating data, and wait for the ready bit to be re-asserted.

31.7.4.1 Dot count

10

15

20

In normal operation the dot counter will wait for the *llu_en* and the ready to be active before starting to count. The dot count will produce data as long as the *phi_llu_ready* is active. If the *phi_llu_ready* signal goes low the count will be stalled.

The dot counter increments for each dot that is processed per line. It is used to determine the line finish position, and the bit select value for reading from the DIU buffers. The counter is reset after each line is processed (*line_fin* signal). It determines when a line is finished by comparing the dot count with the configured line size divided by 2 (note that odd numbers of dots will be rounded down).

```
// define the line finish
                 if (dot cnt[14:0] == line_size[15:1] )then
                   line fin = 1
25
                 else
                   line_fin = 0
                 // determine if word is valid
                 dot_active = ((llu_en == 1) AND (phi llu ready == 1) AND
                 (buf emp == 0))
30
                 // counter logic
                 if (llu go pulse == 1) then
                   dot_cnt = 0
                 elsif ((dot active == 1)AND (line fin == 1)) then
                   dot cnt
                              = 0
35
                 elsif (dot active == 1) then
                   dot cnt = dot cnt + 1
                 else
                   dot cnt
                              = dot cnt
                 // calculate the word select bits
```

```
bit_sel[5:0] := dot_cnt[5:0]
```

The dot generator also maintains a read buffer pointer which is incremented each time a 64-bit word is processed. The pointer is used to address the correct 64-bit dot data word within the DIU buffers. The pointer is reset when Ilu_go_pulse is 1. Unlike the dot counter the read pointer is not reset each line but rounded up the nearest 256-bit word. This allows for more efficient use of the DIU buffers at line finish.

When the dot counter reaches the join point for the dot generator (*join_point*), it jumps to the next 256 bit word in the DIU buffer but continues to read from the next bit position within that word. If the join point coincides with a word boundary, no 256-bit increment is required.

```
10
                 // read pointer logic
                 if (llu_go_pulse == 1) then
                   read adr = 0
                 elsif ((dot_active == 1)AND((dot_cnt[7:0] == 255)OR(line fin
                 == 1)))then
15
                   // end of line round up
                   read adr[3:2] ++
                   read adr[1:0] = 0
                 elsif
                              ((dot active
                                                          1) AND (dot cnt
                 join point) AND (dot cnt[5:0] == 63)) then
20
                   // join point jump 256 bits
                   read adr[1:0] ++
                                                                              //
                 regular increment
                                                                         // join
                   read_adr[3:2] ++
                 point 256 increment
25
                             ((dot_active
                                                         1) AND (dot cnt
                 join point) AND (dot cnt[5:0] != 63)) then
                   // join point jump 256 bits, bottom bits remain the same
                   read adr[3:2] ++
                                                                         // join
                 point 256 increment only
30
                 elsif ((dot_active == 1)AND(dot_cnt[5:0] == 63)) then
                   read adr[3:0] ++
                                                                              //
                 regular increment
```

31.7.5 Fifo fill level

35

40

5

The LLU keeps a running total of the number of lines in the dot line store FIFO. Every time the DWU signals a line end (dwu_llu_line_wr active pulse) it increments the filllevel. Conversely if the LLU detects a line end (line_rd pulse) the filllevel is decremented and the line read is signalled to the DWU via the llu_dwu_line_rd signal.

The LLU fill level block is used to determine when the dot line has enough data stored before the LLU should begin to start reading. The LLU at page start is disabled. It waits for the DWU to write lines to the dot line FIFO, and for the fill level to increase. The LLU remains disabled until the fill level has reached the programmed threshold (fifo_read_thres). When the threshold is reached it signals the LLU to start processing the page by setting <code>llu_en</code> high. Once the LLU has started

processing dot data for a page it will not stop if the *filllevel* falls below the threshold, but will stall is *filllevel* falls to zero.

The line fifo fill level can be read by the CPU via the PCU at any time by accessing the FifoFillLevel register. The CPU must toggle the Go register in the LLU for the block to be correctly initialized at page start and the fifo level reset to zero.

20 31.7.6 DIU interface

5

30

40

DRAM.

31.7.6.1 DIU interface description

The DIU interface block is responsible for determining when dot data needs to be read from DRAM, keeping the dot generators supplied with data and calculating the DRAM read address based on configured parameters, FIFO fill levels and position in a line.

The fill level block enables DIU requests by activating *llu_en* signal. The DIU interface controller then issues requests to the DIU for the LLU buffers to be filled with dot line data (or fill the LLU buffers with null data without requesting DRAM access, if required).

At page start the DIU interface determines which buffers should be filled with null data and which should request DRAM access. New requests are issued until the dot line is completely read from

For each request to the DRAM the address generator calculates where in the DRAM the dot data should be read from. The *color_enable* bus determines which colors are enabled, the interface never issues DRAM requests for disabled colors.

31.7.6.2 Interface controller

The interface controller co-ordinates and issues requests for data transfers from DRAM. The state machine waits in *Idle* state until it is enabled by the LLU controller (*Ilu_en*) and a request for data transfer is received from the write pointer block.

When an active request is received (req_active equals 1) the state machine jumps to the ColorSelect state to determine which colors (color_cnt) in the group need a data transfer. A group is defined as all odd colors or all even colors. If the color isn't enabled (color_enable) the count just increments, and no data is transferred. If the color is enabled, the state machine takes one of

two options, either a null data transfer or an actual data transfer from DRAM. A null data transfer writes zero data to the DIU buffer and does not issue a request to DRAM.

The state machine determines if a null transfer is required by checking the *color_start* signal for that color.

If a null transfer is required the state machine doesn't need to issue a request to the DIU and so jumps directly to the data transfer states (*Data0* to *Data3*). The machine clocks through the 4 states each time writing a null 64-bit data word to the buffer. Once complete the state machine returns to the *ColorSelect* state to determine if further transfers are required.

If the *color_start* is active then a data transfer is required. The state machine jumps to the *Request* state and issue a request to the DIU controller for DRAM access by setting <code>Ilu_diu_rreq</code> high. The DIU responds by acknowledging the request (<code>diu_Ilu_rack</code> equals 1) and then sending 4 64-bit words of data. The transition from <code>Request</code> to <code>Data0</code> state signals the address generator to update the address pointer (<code>adr_update</code>). The state machine clocks through <code>Data0</code> to <code>Data3</code> states each time writing the 64-bit data into the buffer selected by the <code>req_sel</code> bus. Once complete the state machine returns to the <code>ColorSelect</code> state to determine if further transfers are required. When in the <code>ColorSelect</code> state and all data transfers for colors in that group have been serviced (i.e. when <code>color_cnt</code> is 6) the state machine will return to the <code>Idle</code> state. On transition it will update the word counter logic (<code>word_dec</code>) and enabled the request logic (<code>req_update</code>).

A reset or *llu_go_pulse* set to 1 will cause the state machine to jump directly to *ldle*. The controller will remain in *ldle* state until it is enabled by the LLU controller via the *llu_en* signal. This prevents the DIU attempting the fill the DIU buffers before the dot line store FIFO has filled over its threshold level.

31.7.6.3 Color activate

10

15

35

The color activate logic maintains an absolute line count indicating the line number currently being processed by the LLU. The counter is reset when the *llu_go_pulse* is 1 and incremented each time a *line_rd* pulse is received. The count value (*line_cnt*) is used to determine when to start reading data for a color.

The count is implemented as follows:

The color activate logic compares line count with the relative line value to determine when the LLU should start reading data from DRAM for a particular half color. It signals the interface controller block which colors are active for this dot line in a page (via the *color_start* bus). It is used by the interface controller to determine which DIU buffers require null data.

Once the *color_start* bit for a color is set it cannot be cleared in the normal page processing process. The bits must be reset by the CPU at the end of a page by transitioning the *Go* bit and causing a pulse on the *llu_go_pulse* signal.

Any color not enabled by the color_enable bus will never have its color_start bit set.

```
for (i=0; i<12;i++) {
```

```
if ( llu_go_pulse == 1) then
                      col on[i] = 0
                   elsif ( color_enable[i % 6] == 1 ) then
                      col on[i] = 0
5
                   elsif ( line_cnt == color_rel_line[i]) then
                      col on[i] = 1
                 // select either odd or even colors
                 if ( odd even sel == 1 ) then // odd selected
10
                   color start[5:0]
                 {col_on[11],col_on[9],col_on[7],col_on[5],col_on[3],col_on[1
                 ] }
                 else
                                                 // even selected
                   color start[5:0]
15
                 {col on[10],col on[8],col on[6],col on[4],col on[2],col on[0
                 ] }
```

31.7.6.4 Address generator

20

25

30

The address generator block maintains 24 pointers (*current_adr_a[11:0]* and *current_adr_b[11:0]*) to DRAM corresponding to 2 read addresses in the dot line FIFO for each half color. The *current_adr_a* group of pointers are used when the dot generator is feeding printhead channel A, and the *current_adr_b* group of pointers are used when the dot generator is feeding printhead channel B. For each DRAM access the 2 address pointers are updated but only one can be used for an access. The word counter block determines which pointer group should be used to access DRAM, via the pointer select signals (*ptr_sel*). In certain cases (e.g. the join point is not 256-bit aligned and the word is on the join point) the address pointers should not be updated for an access, the word counter block determines the exception cases and indicates to the address generator to skip the update via the *join_stall* signal.

When a DRAM transfer occurs the address pointer is used first and then updated for the next transfer for the color. The pointer used is selected by the *req_sel* and *ptr_sel* buses, and the pointer update is initiated by the *adr_update* signal from the interface controller.

The address update is calculated as follows (pointer group A logic is shown but the same logic is used to update the B pointer group a clock cycle later):

The correct address to use for a transfer is selected by the *ptr_sel* signals from the word counter block. They indicate which set of address pointers should be used based on the current word being transferred from the DRAM and the configured join point values (*join_word*).

```
// select the address pointer to use for access
                if (req sel[0] == 1) then
                                                                      // odd
                pointer selector
15
                   if (ptr_sel[1] == 1) then
                     llu diu radr = current adr b[req sel]
                                                            // latter part
                 of line
                   else
                     llu_diu_radr = current_adr_a[req_sel] // former part
20
                of line
                 else
                                                                     // even
                pointer selector
                   if (ptr sel[0] == 1) then
                     llu diu radr = current adr b[req sel]
                                                              // latter part
25
                 of line
                   else
                                                             // former part
                     llu diu radr = current adr a[req_sel]
                 of line
```

30 31.7.6.5 Write pointer

10

35

40

The write pointer logic maintains the buffer write address pointers, determines when the DIU buffers need a data transfer and signals when the DIU buffers are empty. The write pointer determines the address in the DIU buffer that the data should be transferred to.

The write pointer logic compares the read and write pointers of each DIU buffer to determine which buffers require data to be transferred from DRAM, and which buffers are empty (the buf_emp signals).

Buffers are grouped into odd and even buffers, if an odd buffer requires DRAM access the odd_pend signals will be active, if an even buffer requires DRAM access the even_pend signals will be active. If both odd and even buffers require DRAM access at exactly the same time, the even buffers will get serviced first. If a group of odd buffers are being serviced and an even buffer becomes pending, the odd group of buffers will be completed before the starting the even group, and vice versa.

If any buffer requires a DRAM transfer, the logic will indicate to the interface controller via the req_active signal, with the odd_even_sel signal determining which group of buffers get serviced. The interface controller will check the color_enable signal and issue DRAM transfers for all enabled colors in a group. When the transfers are complete it tells the write pointer logic to update the request pending via req_update signal.

The *req_sel[3:0]* signal tells the address generator which buffer is being serviced, it is constructed from the *odd_even_sel* signal and the *color_cnt[2:0]* bus from the interface controller. When data is being transferred to DRAM the word pointer and write pointer for the corresponding buffer are updated. The *req_sel* determines which pointer should be incremented.

10 The write pointer logic operates the same way regardless of whether the transfer is null or not.

5

```
// determine which buffers need updates
                 buf emp[1:0] = 0
                 odd pend
15
                 even pend
                 if ( wr_adr[0][3:2] == rd adr[0][3:2] )
                      even_pend = 1
                 if ( wr_adr[1][3:2] == rd_adr[1][3:2] )
                      odd_pend = 1
20
                 // determine if buffers are empty
                 if ((wr adr[0][3:0] == rd adr[0][3:0])) then
                      buf emp[0] = 1
                 if ((wr adr[1][3:0] == rd adr[1][3:0])) then
                      buf_emp[1] = 1
25
                 // fixed servicing order, only update when controller
                 dictates so
                 if (req_update == 1) then {
                   if (even pend == 1) then
                                                    // even always first
                      odd even sel = 0
30
                      req_active
                   elsif (odd pend == 1 ) then
                                                    // then check odd
                      odd even sel = 0
                      req_active
                                                    // nothing active
                   else
35
                      odd even sel = 0
                      req_active
                   }
                 // selected requestor
                 req sel[3:0]
                                     {color cnt[2:0],odd even sel}
                                                                            //
40
                 concatentation
```

The write address pointer logic consists of 2 2-bit counters and a word select pointer. The counters are reset when *llu_go_pulse* is one. The word pointer (*word_ptr*) is common to all buffers and is used to write 64-bit words into the DIU buffer. It is incremented when *buf_rd_en* is active.

When a group of buffers are updated the state machine increments the write pointer (wr_ptr[odd_even_sel]) via the group_fin signal. A concatenation of the write pointer and the word pointer are use to construct the buffer write address. The write pointers are not reset at the end of each line.

5

```
// determine which pointer to update
                 if (llu go pulse == 1) then
                  wr ptr[1:0] = 0
                   word ptr
10
                 elsif (buf_rd_en == 1) then
                   word_ptr++
                   wr_en[req_sel] = 1
                 elsif (group fin = 1 ) then
                  wr_ptr[odd_even_sel]++
15
                // create the address from the write pointer and word
                pointer
                wr adr[odd even sel] = {wr ptr[odd even sel], word ptr}
                                                                           11
                 concatenation
```

20

25

30

35

31.7.6.6 Word count

The word count logic maintains 2 counters to track the number of words transferred from DRAM per line, one counter for odd data, and one counter for even. On receipt of a <code>llu_go_pulse</code>, the counters are initialized to a <code>join_word</code> value (number of words to the join point for that printhead channel) and the pointer select values to zero (<code>ptr_sel</code>). When a group of words are transferred to DRAM as indicated by the <code>word_dec</code> signal from the interface controller, the corresponding counter is decremented. The counter to decrement is indicated by the <code>odd_even_sel</code> signal from the write pointer block (even = 0, odd = 1).

When a counter is zero and the *ptr_sel* is zero, the counter is re-initialized to the second *join_word* value and *ptr_sel* is inverted. The counter continues to count down to zero each time a *word_dec* signal is received. When a counter is zero and the *ptr_sel* is one, it signals the end of a line (the *last_wd* signal) and initializes the counter to the first *join_point* value for the next line transfer.

The *ptr_sel* signal is used in the address generator to select the correct address pointer to use for that particular access.

```
// need to
                 elsif (word dec == 1) then {
                 decrement one word counter
                   if (odd_even_sel == 0) then
                                                              // even counter
                 update
 5
                     if (word_cnt[0] == 0) then
                        word cnt[0] = join word[ptr sel[0]] // re-initialize
                 pointer
                        ptr_sel[0] = ~(ptr_sel[0])
                                                              // determine if
                        if (ptr sel[0] == 1) then
10
                 this the last word
                          last wd = 1
                     else
                        word cnt[0] --
                                                                 . // normal
                 decrement
15
                                                                // odd counter
                   else
                 update
                     if (word_cnt[1] == 0) then
                        word_cnt[1] = join_word[ptr_sel[1]] // re-initialize
                 pointer
20
                        ptr sel[1] = ~(ptr sel[1])
                        if (ptr sel[1] == 1) then
                                                              // determine if
                 this the last word
                          last wd = 1
                     else
25
                        word cnt[1] --
                                                                    // normal
                 decrement
                   }
```

The word count logic also determines if the current word to be transferred is the join word, and if so it determines if it is aligned on a 256-bit boundary or not. If the join point is aligned to a boundary there is no need to prevent the address counter from incrementing, otherwise the address pointers are stalled for that word transfer (*join_stall*).

The word count logic also determines when a complete line has been read from DRAM, it then signals the fifo fill level logic in both the LLU and DWU (via *line_rd* signal) that a complete line has been read by the LLU (*llu_dwu_line_rd*).

```
// line finish logic
if (llu_go_pulse == 1) then
    line_fin = 0
    line_rd = 0
elsif ((last_wd == 1) AND (line_fin == 0)) then
```

30

32 PrintHead Interface (PHI)

32.1 OVERVIEW

15

20

25

30

The Printhead interface (PHI) accepts dot data from the LLU and transmits the dot data to the printhead, using the printhead interface mechanism. The PHI generates the control and timing signals necessary to load and drive the bi-lithic printhead. The CPU determines the line update rate to the printhead and adjusts the line sync frequency to produce the maximum print speed to account for the printhead IC's size ratio and inherent latencies in the syncing system across multiple SoPECs.

The PHI also needs to consider the order in which dot data is loaded in the printhead. This is dependent on the construction of the printhead and the relative sizes of printhead ICs used to create the printhead. See Bi-lithic Printhead Reference document for a complete description of printhead types [10].

The printing process is a real-time process. Once the printing process has started, the next printline's data must be transferred to the printhead before the next line sync pulse is received by the printhead. Otherwise the printing process will terminate with a buffer underrun error.

The PHI can be configured to drive a single printhead IC with or without synchronization to other SoPECs. For example the PHI could drive a single IC printhead (i.e. a printhead constucted with one IC only), or dual IC printhead with one SoPEC device driving each printhead IC.

The PHI interface provides a mechanism for the CPU to directly control the PHI interface pins, allowing the CPU to access the bi-lithic printhead to:

- determine printhead temperature
- test for and determine dead nozzles for each printhead IC
- initialize each printhead IC
- pre-heat each printhead IC
- Figure 277 shows a high level data flow diagram of the PHI in context.

32.2 PRINTHEAD MODES OF OPERATION

The printhead has 8 different modes of operations (although some modes are re-used). The mode of operation is defined by the state of the output pins *phi_lsyncl* and *phi_readl* and the internal printhead mode register. The modes of operation are defined in Table 210.

Table 210. Printhead modes of operation

Name	Internal Mode	phi _re	phi_ls	State	Description
		adl	yncl		
NORMAL	XXX	1	1	N/A	Normal print mode, dot data is
					clocked into the printhead shift
					register, on each falling edge of
					phi_srclk
DOT_LOAD/	xxx	1	0	phi_frclk=0	Dot Load Mode, data stored in the
FIRE_INIT					dot shift register is transferred into
					the dot latch on the falling edge of
					phi_lsyncl, and latched in on the
					rising edge of <i>phi_lsyncl</i>
				phi_srclk=1	Fire load mode. Parameter for
					generating fire pattern are loaded
					into generator, data on
					phi_ph_data[1:0][0] is clocked into
					the generator on each rising edge of
					phi_frclk
NOZZLE_RE	001	0	1	N/A	Reset Nozzle Test mode. Reset the
SET					state on nozzle test.
CMOS_TEST	111	0	1	N/A	CMOS test mode.
FIRE_GEN	000	0	1	N/A	Fire Initialise mode. The initialised
					generator creates the fire pattern
					and shift select pattern. The pattern
					is clocked into the fire shift register
					and select shift register on the rising
					edge of <i>phi_frclk</i>
TEMP_TEST	010	0	0	N/A	Temperature test output.
NOZZLE_TE	001	0	0	N/A	Nozzle test output.
ST					The result of a nozzle test is output
					on <i>phi_frclk_i</i> .
L			<u></u>		<u> </u>

32.3 DATA RATE EQUALIZATION

5

The LLU can generate dot data at the rate of 12 bits per cycle, where a cycle is at the system clock frequency. In order to achieve the target print rate of 30 sheets per minute, the printhead needs to print a line every 100µs (calculated from 300mm @ 65.2 dots/mm divided by 2 seconds =~ 100µsec). For a 7:3 constructed printhead this means that 9744 cycles at 320Mhz is quick enough to transfer the 6-bit dot data (at 2 bits per cycle). The input FIFOs are used to de-couple the read and write clock domains as well as provide for differences between consume and fill rates of the PHI and LLU.

Nominally the system clock (*pclk*) is run at 160Mhz and the printhead interface clock (*doclk*) is at 320Mhz.

If the PHI was to transfer data at the full printhead interface rate, the transfer of data to the shorter printhead IC would be completed sooner than the longer printhead IC. While in itself this isn't an issue it requires that the LLU be able to supply data at the maximum rate for short duration, this requires uneven bursty access to DRAM which is undesirable. To smooth the LLU DRAM access requirements over time the PHI transfers dot data to the printhead at a pre-programmed rate, proportional to the ratio of the shorter to longer printhead ICs.

The printhead data rate equalization is controlled by *PrintHeadRate[1:0]* registers (one per printhead IC). The register is a 16 bit bitmap of active clock cycles in a 16 clock cycle window. For example if the register is set to 0xFFFF then the output rate to the printhead will be full rate, if it's set to 0xF0F0 then the output rate is 50% where there is 4 active cycles followed by 4 inactive cycles and so on. If the register was set to 0x0000 the rate would be 0%. The relative data transfer rate of the printhead can be varied from 0-100% with a granularity of 1/16 steps.

Table 211. Example rate equalization values for common printheads

Printhead Ratio A:B	Printhead A rate	Printhead B rate (%)	
	(%)		
8:2	0xFFFF (100%)	0x1111 (25%)	
7:3	0xFFFF (100%)	0x5551 (43.7%)	
6:4	0xFFFF (100%)	0xF1F2 (68.7%)	
5:5	0xFFFF (100%)	0xFFFF (100%)	

If both printhead ICs are the same size (e.g. a 5:5 printhead) it may be desirable to reduce the data rate to both printhead ICs, to reduce the read bandwidth from the DRAM.

20 32.4 DOT GENERATE AND TRANSMIT ORDER

5

10

15

25

30

Several printhead types and arrangements exists (see [10] for other arrangements). The PHI is capable of driving all possible configurations, but for the purposes of simplicity only one arrangement (arrangement 1 - see [10] for definition) is described in the following examples. The structure of the printhead ICs dictate the dot transmit order to each printhead IC. The PHI accepts two streams of dot data from the LLU, one even stream the other odd. The PHI constructs the dot transmit order streams from the dot generate order received from the LLU. Each stream of data has already been arranged in increasing or decreasing dot order sense by the DWU. The exact sense choice is dependent on the type of printhead ICs used to construct the printhead, but regardless of configuration the odd and even stream should be of opposing sense.

The dot transmit order is shown in Figure 281. Dot data is shifted into the printhead in the direction of the arrow, so from the diagram (taking the type 0 printhead IC) even dot data is transferred in increasing order to the mid point first (0, 2, 4, ..., m-6, m-4, m-2), then odd dot data in decreasing order is transferred (m-1, m-3, m-5,...., 5, 3, 1). For the type 1 printhead IC the order is reversed, with odd dots in increasing order transmitted first, followed by even dot data in

decreasing order. Note for any given color the odd and even dot data transferred to the printhead ICs are from different dot lines, in the example in the diagram they are separated by 5 dot lines. Table 212 shows the transmit dot order for some common A4 printheads. Different type printheads may have the sense reversed and may have an odd before even transmit order or vice versa.

Table 212. Example printhead ICs, and dot data transmit order for A4 (13824 dots) page

Size	Dots	Dot Order

32.4.1 Dual Printhead IC

10

15

5

The LLU contains 2 dot generator units. Each dot generator reads dot data from DRAM and generates a stream of dots in increasing or decreasing order. A dot generator can be configured to produce odd or even dot data streams, and the dot sense is also configurable. In Figure 281 the odd dot generator is configured to produce odd dot data in decreasing order and the even dot generator produces dot data in increasing order. The LLU takes care of any vertical misalignment between the 2 printhead ICs, presenting the PHI with the appropriate data ready to be transmitted to the printhead.

In order to reconstruct the dot data streams from the generate order to the transmit order, the connection between the generators and transmitters needs to be switched at the mid point. At line start the odd dot generator feeds the type 1 printhead, and the even dot generator feeds the type 0 printhead. This continues until both printheads have received half the number of dots they require (defined as the mid point). The mid point is calculated from the configured printhead size registers (*PrintHeadSize*). Once both printheads have reached the mid point, the PHI switches the connections between the dot generators and the printhead, so now the odd dot generator feeds the type 0 printhead and the even dot generator feeds the type 1 printhead. This continues until the end of the line.

10 It is possible that both printheads will not be the same size and as a result one dot generator may reach the mid point before the other. In such cases the quicker dot generator is stalled until both dot generators reach the mid point, the connections are switched and both dot generators are restarted.

Note that in the example shown in Figure 281 the dot generators could generate an A4 line of data in 6912 cycles, but because of the mismatch in the printhead IC sizes the transmit time takes 9744 cycles.

32.4.2 Single printhead IC

15

20

25

40

In some cases only one printhead IC may be connected to the PHI. In Figure 282 the dot generate and transmit order is shown for a single IC printhead of 9744 dots width. While the example shows the printhead IC connected to channel A, either channel could be used. The LLU generates odd and even dot streams as normal, it has no knowledge of the physical printhead configuration. The PHI is configured with the printhead size (*PrintHeadSize[1]* register) for channel B set to zero and channel A is set to 9744.

Note that in the example shown in Figure 283 the dot generators could generate an 7 inch line of data in 4872 cycles, but because the printhead is using one IC, the transmit time takes 9744 cycles, the same speed as an A4 line with a 7:3 printhead.

32.4.3 Summary of generate and transmit order requirements
In order to support all the possible printhead arrangements, the PHI (in conjuction with the LLU/DWU) must be capable of re-ordering the bits according to the following criteria:

- Be able to output the even or odd plane first.
 - Be able to output even and odd planes independently.
 - Be able to reverse the sequence in which the color planes of a single dot are output to the printhead.

32.5 PRINT SEQUENCE

The PHI is responsible for accepting dot data streams from the LLU, restructuring the dot data sequence and transferring the dot data to each printhead within a line time (i.e before the next line sync).

Before a page can be printed the printhead ICs must be initialized. The exact initialization sequence is configuration dependent, but will involve the fire pattern generation initialization and other optional steps. The initialization sequence is implemented in software.

Once the first line of data has been transferred to the printhead, the PHI will interrupt the CPU by asserting the *phi_icu_print_rdy* signal. The interrupt can be optionally masked in the ICU and the CPU can poll the signal via the PCU or the ICU. The CPU must wait for a print ready signal in all printing SoPECs before starting printing.

Once the CPU in the PrintMaster SoPEC is satisfied that printing should start, it triggers the LineSyncMaster SoPEC by writing to the *PrintStart* register of all printing SoPECs. The transition of the *PrintStart* register in the LineSyncMaster SoPEC will trigger the start of *IsyncI* pulse generation. The PrintMaster and LineSyncMaster SoPEC are not necessarily the same device, but often are the same. For a more in depth definition see section 12.1.1 Multi-SoPEC systems on page 105.

Writing a 1 to the *PrintStart* register enables the generation of the line sync in the LineSyncMaster which is in turn used to align all SoPECs in a multi-SoPEC system. All printhead signaling is aligned to the line sync. The *PrintStart* is only used to align the first line sync in a page.

printhead is now printing, so the PHI can begin to transfer the next line of data to the printhead. When the transfer is complete the PHI will wait for the next line sync pulse before repeating the cycle. If a line sync arrives before a complete line is transferred to the printhead (i.e. a buffer error) the PHI generates a buffer underrun interrupt, and halts the block.

When a SoPEC receives a line sync pulse it means that the line previously transferred to the

For each line in a page the PHI must transfer a full line of data to the printhead before the next line sync is generated or received.

32.5.1 Sync pulse control

15

20

35

If the PHI is configured as the LineSyncMaster SoPEC it will start generating line sync signals LsyncPre number of pclk cycles after PrintStart register rising transition is detected. All other signals in the PHI interface are referenced from the rising edge of phi_lsyncl signal.

If the SoPEC is in line sync slave mode it will receive a line sync pulse from the LineSyncMaster SoPEC through the *phi_lsyncl* pin which will be programmed into input mode. The *phi_lsyncl* input pin is treated as an asynchronous input and is passed through a de-glitch circuit of programmable de-glitch duration (*LsyncDeglitchCnt*).

The *phi_lsyncl* will remain low for *LsyncLow* cycles, and then high for *LsyncHigh* cycles. The phi_lsyncl profile is repeated until the page is complete. The period of the *phi_lsyncl* is given by *LsyncLow* + *LsyncHigh* cycles. Note that the *LsyncPre* value is only used to vary the time between the generation of the first *phi_lsyncl* and the *PageStart* indication from the CPU. See Figure 284 for reference diagram.

If the SoPEC device is in line sync slave mode, the *LsyncHigh* register specifies the minimum allowed *phi_lsyncl* period. Any *phi_lsyncl* pulses received before the *LsyncHigh* has expired will trigger a buffer underrun error.

32.5.2 Shift register signal control

Once the PHI receives the line sync pulse, the sequence of data transfer to the printhead begins. All PHI control signals are specified from the rising edge of the line sync.

The phi_srclk (and consequently phi_ph_data) is controlled by the SrclkPre, SrclkPost registers. The SrclkPre specifies the number of pclk cycles to wait before beginning to transfer data to the printhead. Once data transfer has started, the profile of the phi_srclk is controlled by PrintHeadRate register and the status of the PHI input FIFO. For example it is possible that the input FIFO could empty and no data would be transferred to the printhead while the PHI was waiting. After all the data for a printhead is transferred to the PHI, it counts SrclkPost number of pclk cycles. If a new phi_lsyncl falling edge arrives before the count is complete the PHI will generate a buffer underrun interrupt (phi_icu_underrun).

32.5.3 Firing sequence signal control

- The profile of the phi_frclk pulses per line is determined by 4 registers FrclkPre, FrclkLow, FrclkHigh, FrclkNum. The FrclkPre register specifies the number of cycles between line sync rising edge and the phi_frclk pulse high. It remains high for FrclkHigh cycles and then low for FrclkLow cycles. The number of pulses generated per line is determined by FrclkNum register. The total number of cycles required to complete a firing sequence should be less than the phi_lsyncl period i.e. ((FrclkHigh + FrclkLow) * FrclkNum) + FrclkPre < (LsyncLow + LsyncHigh). Note that when in CPU direct control mode (PrintHeadCpuCtrl=1) and PrintHeadCpuCtrlMode[x] =1, the frclk generator is triggered by the transition of the FireGenSoftTrigger[0] bit from 0 to 1. Figure 284 details the timing parameters controlling the PHI. All timing parameters are measured in number of pclk cycles.</p>
- 20 32.5.4 Page complete The PHI counts the number of lines processed through the interface. The line count is initialised to the PageLenLine and decrements each time a line is processed. When the line count is zero it pulses the phi_icu_page_finish signal. A pulse on the phi_icu_page_finish automatically resets the PHI Go register, and can optionally cause an interrupt to the CPU. Should the page terminate

abnormally, i.e. a buffer underrun, the Go register will be reset and an interrupt generated.

32.5.5 Line sync interrupt

The PHI will generate an interrupt to the CPU after a predefined number of line syncs have occured. The number of line syncs to count is configured by the *LineSyncInterrupt* register. The interrupt can be disabled by setting the register to zero.

30 32.6 DOT LINE MARGIN

25

35

40

The PHI block allows the generation of margins either side of the received page from the LLU block. This allows the page width used within PEP blocks to differ from the physical printhead size.

This allows SoPEC to store data for a page minus the margins, resulting in less storage requirements in the shared DRAM and reduced memory bandwidth requirements. The difference between the dot data line size and the line length generated by the PHI is the dot line margin length. There are two margins specified for any sheet, a margin per printhead IC side. The margin value is set by programming the *DotMargin* register per printhead IC. It should be noted that the *DotMargin* register represents half the width of the actual margin (either left or right margin depending on paper flow direction). For example, if the margin in dots is 1 inch (1600)

dots), then *DotMargin* should be set to 800. The reason for this is that the PHI only supports margin creation cases 1 and 3 described below.

See example in Figure 284.

In the example the margin for the type 0 printhead IC is set at 100 dots (DotMargin==100),

- 5 implying an actual margin of 200 dots.
 - If case one is used the PHI takes a total of 9744 *phi_srclk* cycles to load the dot data into the type 0 printhead. It also requires 9744 dots of data from the LLU which in turn gets read from the DRAM. In this case the first 100 and last 100 dots would be zero but are processed though the SoPEC system consuming memory and DRAM bandwidth at each step.
- In case 2 the LLU no longer generates the margin dots, the PHI generates the zeroed out dots for the margining. The phi_srclk still needs to toggle 9744 times per line, although the LLU only needs to generate 9544 dots giving the reduction in DRAM storage and associated bandwidth. The case 2 senario is not supported by the PHI because the same effect can be supported by means of case 1 and case 3.
- 15 If case 3 is used the benefits of case 2 are achieved, but the *phi_srclk* no longer needs to toggle the full 9744 clock cycles. The *phi_srclk* cycles count can be reduced by the margin amount (in this case 9744-100=9644 dots), and due to the reduction in *phi_srclk* cycles the *phi_lsyncl* period could also be reduced, increasing the line processing rate and consequently increasing print speed. Case 3 works by shifting the odd (or even) dots of a margin from line Y to become the
- even (or odd) dots of the margin for line Y-4, (Y-5 adjusted due to being printed one line later).

 This works for all lines with the exception of the first line where there has been no previous line to generate the zeroed out margin. This situation is handled by adding the line reset sequence to the printhead initialization procedure, and is repeated between pages of a document.
 - 32.7 DOT COUNTER
- For each color the PHI keeps a dot usage count for each of the color planes (called AccumDotCount). If a dot is used in particular color plane the corresponding counter is incremented. Each counter is 32 bits wide and saturates if not reset. A write to the DotCountSnap register causes the AccumDotCount[N] values to be transferred to the DotCount[N] registers (where N is 5 to 0, one per color). The AccumDotCount registers are cleared on value transfer.
- 30 The *DotCount[N]* registers can be written to or read from by the CPU at any time. On reset the counters are reset to zero.

The dot counter only counts dots that are passed from the LLU through the PHI to the printhead. Any dots generated by direct CPU control of the PHI pins will not be counted.

32.8 CPU IO CONTROL

- The PHI interface provides a mechanism for the CPU to directly control the PHI interface pins, allowing the CPU to access the bi-lithic printhead:
 - Determine printhead temperature
 - Test for and determine dead nozzles for each printhead IC
 - Printhead IC initialization
- 40 Printhead pre-heat function

The CPU can gain direct control of the printhead interface connections by setting the
PrintHeadCpuCtrl register to one. Once enabled the printhead bits are driven directly by the
PrintHeadCpuOut control register, where the values in the register are reflected directly on the
printhead pins and the status of the printhead input pins can be read directly from the
PrintHeadCpuIn. The direction of pins is controlled by programming PrintHeadCpuDir register.
The register to pin mapping is as follows:

Table 213. CPU control and status registers mapping to printhead interface

Register Name	bits	Printhead pin
PrintHeadCpuOut	0	phi_lsyncl_o
	1	phi_frclk_o
	2	Reserved
,	4:3	phi_ph_data_o[0][1:0]
	6:5	phi_ph_data_o[1][1:0]
	8:7	phi_srclk[1:0]
	9	phi_readl
PrintHeadCpuDir	0	phi_lsyncl_e direction control
		1 - output mode
		0 - input mode
	1	phi_frclk_e direction control
		1 - output mode
		0 - input mode
	2	Reserved
PrintHeadCpuln	0	phi_lsyncl_i
	1	phi_frclk_i
	2	Reserved

It is important to note that once in *PrintHeadCpuCtrl* mode it is the responsibility of the CPU to drive the printhead correctly and not create situations where the printhead could be destroyed such as activating all nozzles together.

The *phi_srclk* is a double data rate clock (DDR) and as such will clock data on both edges in the printhead.

Note the following procedures are based on current printhead capabilities, and are subject to change.

32.9 IMPLEMENTATION

32.9.1 Definitions of I/O

Table 214. Printhead interface I/O definition

Port name	Pins	1/0	Description
Clocks and Resets		_L_	
Pclk	1	ln	System Clock

10

15

Doclk 1		ln .	Data out clock (2x pclk) used to transfer data to
			printhead
prst_n 1		ln	System reset, synchronous active low. Synchronous to
			pc/k
dorst_n 1		ln	System reset, synchronous active low. Synchronous to
			docik
General			
phi_icu_print_rdy 1	•	Out	Indicates that the first line of data is transferred to the
			printhead Active high.
phi_icu_page_finish 1		Out	Indicates that data for a complete page has transferred.
			Active high
phi_icu_underrun 1		Out	Indicates the PHI has detected a buffer underrun. Active
			high
phi_icu_linesync_int 1		Out	Indicates the PHI has detected LineSyncInterrupt
			number of line syncs.
Debug			
debug_data_valid 1		ln	Output debug data valid to be muxed on to the PHI pin
debug_cntrl 1		ln	Control signal for the PHI to indicate whether or not the
			debug data valid (and pclk) should be selected by the
			pin mux. Active high.
LLU Interface			-
llu_phi_data[1:0][5:0] 2	2x6	ln	Dot Data from LLU to the PHI, each bit is a color plane
			5 downto 0.
			Bus 0 - Even dot data stream
			Bus 1 - Odd dot data stream
			Data is active when corresponding bit is active in
			<i>llu_phi_avail</i> bus
phi_llu_ready[1:0] 2	?	Out	Indicates that PHI is ready to accept data from the LLU
			0 - Even dot data stream
			1 - Odd dot data stream
llu_phi_avail[1:0] 2	2	ln	Indicates valid data present on corresponding
			llu_phi_data.
			0 - Even dot data stream
			1 - Odd dot data stream
Printhead Interface			
phi_ph_data[1:0][1:0] 2	2x2	Out	Dot data output to printhead. Each bus to each
			printhead contains 2 bits of data
			Bus 0 - Printhead channel A
		l	

phi_srclk[1:0]	2	Out	Dot data shift clock used to clock in printhead data, data	
			is shifted on both edges of clock(i.e. double data rate	
			DDR).	
			Bus 0 - Printhead channel A	
			Bus 1 - Printhead channel B	
phi_readl	1	Out	Common printhead mode control. Used in conjunction	
			with phi_lsyncl to determine the printhead mode	
			0 - SoPEC receiving, printhead driving	
			1 - SoPEC driving, printhead receiving	
phi_frclk_o	1	Out	Common Fire pattern clock needs to toggle once per	
			fire cycle	
phi_frclk_e	1	In	phi_frclk_o output enable, when high phi_frclk_o pin is	
			driving	
phi_frclk_l	1	ln	phi_frclk_i input from printhead	
phi_lsyncl_o	1	Out	Capture dot data for next print line, output mode	
phi_lsyncl_e	1	In	phi_Isyncl output enable, when high phi_Isyncl pin is	
			driving	
phi_lsyncl_i	1	ln	Line Sync Pulse from Master SoPEC	
PCU Interface	<u> </u>			
pcu_phi_sel	1	In	Block select from the PCU. When pcu_phi_sel is high	
			both <i>pcu_adr</i> and <i>pcu_dataout</i> are valid.	
pcu_rwn	1	In	Common read/not-write signal from the PCU.	
pcu_adr[7:2]	6	In	PCU address bus. Only 6 bits are required to decode	
			the address space for this block.	
pcu_dataout[31:0]	32	ln	Shared write data bus from the PCU.	
phi_pcu_rdy	1	Out	Ready signal to the PCU. When phi_pcu_rdy is high it	
			indicates the last cycle of the access. For a write cycle	
			this means pcu_dataout has been registered by the	
			block and for a read cycle this means the data on	
			phi_pcu_datain is valid.	
phi_pcu_datain[31:0]	32	Out	Read data bus to the PCU.	
L	٠	<u> </u>	<u> </u>	

32.9.2 PHI sub-block partition

32.9.3 Configuration registers

5

The configuration registers in the PHI are programmed via the PCU interface. Refer to section 21.8.2 on page 321 for a description of the protocol and timing diagrams for reading and writing registers in the PHI. Note that since addresses in SoPEC are byte aligned and the PCU only supports 32-bit register reads and writes, the lower 2 bits of the PCU address bus are not required to decode the address space for the PHI. When reading a register that is less than 32 bits wide

zeros should be returned on the upper unused bit(s) of *phi_pcu_datain*. Table 215 lists the configuration registers in the PHI

Table 215. PHI registers description

Address	Register	#bits	Reset	Description
PHI_base+ Control Registers				
0x00	Reset	1	0x1	Active low synchronous reset, self de-
	reset			activating. A write to this register will
				cause a PHI block reset.
0x04	Go	1	0x0	Active high bit indicating the PHI is
0.04	Go	'	OXU	
				programmed and ready to use. A low
				to high transition will cause PHI block
				internal state to reset. Will be
				automatically reset if a page finish or a
				buffer underrun is detected.
General Control				•
0x08	PageLenLine	32	0x0000	Specifies the number of dot lines in a
			_0000	page.
				Indicates the number of lines left to
				process in this page while the PHI is
				running (Working register)
0x0c	PrintStart	1	0x0	A high level enables printing to start
				via the generation of line syncs in a
				master, and acceptance of line syncs
				in a slave. Can be set in advance of
				the print ready signal.
0x10-0x14	DotMargin[1:0]	2x16	0x0000	Specifies for each printhead IC, the
				width of the margin in dots divided by
				2.
				Value must be divisible by 2 (i.e. the
				low bit must be 0)
				0 - Printhead IC Channel A
				1 - Printhead IC Channel B
0x18-0x2C	DotCount[5:0]	6x32	0x0000	Indicates the number of Dots used for
			_0000	a particular color, where N specifies a
				color from 0 to 5. Value valid after a
				write access to <i>DotCountSnap</i>
0x30	DotCountSnap	1	0x0	Write access causes the
	<u> </u>	1	1	

		· · · · ·		AccumDotCount values to be
				transferred to the <i>DotCount</i> registers.
				The AccumDotCount are reset
				afterwards.(Reads as zero)
0x34	PhiHeadSwap	1	0x0	Controls which signals are connected
				to printhead channels A and B
				0 - Normal, specifies bit 0 is channel A,
				bit 1 is channel B
				1 - Swapped, specifies bit 0 is channel
				B, bit 1 is channel A.
0x38	PhiMode	1	0x0	Indicates whether the PHI is operating
				in master or slave mode
				0 - Slave Mode
				1 - Master Mode
0x3C-0x40	PhiSerialOrder	2x1	0x0	Specifies the serialization order of dots
	,			before transfer to the printhead.
				Bus 0 - Printhead Channel A
				Bus 1 - Printhead Channel B
	1			If set to zero the order is dot[1:0], then
				dot[3:2] then dot[5:4]. If set to one then
				the order is dot[5:4], dot[3:2], dot[1:0].
0x44-0x48	PrintHeadSize	2x16	0x0000	Specifies the number of non-margin
	1			dots in the printhead ICs (must be
				even). If margining is to be used then
				the configured <i>PrintHeadSize</i> should
				be adjusted by the dot margin value
				i.e. PrintHeadSize = (Physical-
				PrintHeadSize - (DotMargin * 2)).
				Value must be divisible by 2 (i.e. the
				low bit must be 0)
				Bus 0 - Specifies printhead on
:				Channel A
				Bus 1 - Specifies printhead on
				Channel B
CPU Direct PHI Contr	ol (See Table 21	3)	J	Charlie D
